Several works on reptile reproduction have described inter-clutch egg size variation. For example, egg size has been shown to vary seasonally in lizards (e.g., Nussbaum 1981), and is limited by female size in several turtle species (e.g., Congdon and Gibbons 1983, 1987; Rowe 1994). However, no works have described intra-clutch variations in egg size and shape.

Egg ellipticity (width/length) is rather constant in lizard species (Werner 1989), but is highly variable in the viperid snake *Trimeresurus flavoviridis,* ranging from 0.286 to 0.691 (Nishimura and Kamura 1993). This large variation is partly due to the fact that smaller females produce slender eggs in *T. flavoviridis* (Ford and Seigel 1989; Nishimura 1983), indicating that egg shape is influenced by maternal size. The present work describes another source of variation, intra-clutch variation, in egg shape of *T. flavoviridis*.

Between 1981 and 1995, 256 gravid *Trimeresurus flavoviridis* were collected from the Okinawa Islands, south of Japan (26°30'N, 127°45'E). Of these, 135 snakes oviposited whole clutches, 90 snakes died or were sacrificed before oviposition, and 31 snakes died after ovipositing some of the oviductal eggs. Weight, length, and width of oviposited eggs were measured within 36 h (usually <16 h) of oviposition. Oviductal eggs were measured after freezing the females. I classified the egg shape into three categories: normal, peaked at one side, and weakly peaked at one side.

All embryonated and oviposited eggs had white shells with several scar marks on them. I considered these eggs to be fertilized. Most unfertilized oviposited eggs were small and irregularly shaped. Some oviductal immature eggs had normal shapes with yellowish and scarless shells. I observed embryos in some of these eggs (see Koba et al. 1970). In the present work I used data from fertilized eggs and those of normally shaped oviductal eggs.

As noted above, the means of egg width (Ford and Seigel 1989; Nishimura 1983) and length (Nishimura 1983) vary with maternal size of *T. flavoviridis*. Therefore, the variation of egg size in a clutch was described as a proportion to the mean of the other eggs.

Arrangement of oviductal eggs.—Two females contained follicles as large as oviductal eggs. One had three eggs and two large follicles in the right oviduct and in the left ovary, respectively, and the other had five eggs and two eggs in the right and left oviduct, respectively, and one large follicle in the left ovary. Shiroma (1993) suggested that several eggs ovulated from the right or left ovary move to the opposite oviduct in *T. flavoviridis*.

All pre-ovipositional females with complete ovulation had eggs in both oviducts. Of these I checked the egg arrangements in 54 females. In 48 females all eggs in the right oviduct were situated anterior to those in the left oviduct. Among the remaining six females, one egg in the right oviduct was positioned posteriorly to (three clutches) or side by side with (three clutches) eggs in the left oviduct. The former type of clutch has been described by Koba et al. (1970) who dissected 17 gravid females in July (ovipositional season). They reported that two females had eggs only in the right oviduct. However, it is conceivable that these two females partially oviposited before dissection and originally contained eggs in the left oviduct.

Variation in egg shape of pre-oviposited clutch.—Compared to the eggs positioned in the middle of the abdominal cavity, the eggs positioned most anteriorly and posteriorly were longer and slightly smaller in width, and the weight of these eggs deviated only slightly from the average (Table 1).

Among 18 eggs of peaked shape, 15 were positioned anteriorly or posteriorly, and the remaining three eggs were situated side by side with eggs in the other oviduct. The peaked points of the eggs were directed to either the anterior or posterior edge of the egg row.

Full term clutches were positioned between the gall bladder and vent. The most posterior egg was positioned along the left kidney and opposite oviduct (usually the right oviduct) in the trunk of decreased width. Females with full term clutches or just after oviposition had consumed a considerable proportion of the fat bodies. However, most of the anterior fat body, which had not been consumed, decreased the space for the most anterior egg. The slender and peaked shape in the most anterior and posterior eggs may be due to the space constraints at both ends of the abdominal cavity.

TABLE 1. Relative size of the most anteriorly and posteriorly positioned eggs in the abdominal cavity of *Trimeresurus flavoviridis*. The measurements of the eggs of pre-ovipositional females (died in the oviposition season) were divided by the respective mean of the eggs ($N \geq 2$) intermediately positioned in each clutch. The most anterior eggs of partially oviposited females were left in the oviduct for more than one day and the measurements were divided by the respective mean of oviposited eggs ($N \geq 2$) in each clutch.

	Length		Width		Mass	
	N	Mean ± S.E.	N	Mean ± S.E.	N	Mean ± S.E.
Pre-ovipositional female						
Most anterior egg	36	1.115 ± 0.017	32	0.984 ± 0.016	33	1.049 ± 0.033
Most posterior egg	35	1.127 ± 0.015	31	0.961 ± 0.012	32	1.014 ± 0.014
Partially oviposited female						
Most anterior egg	10	1.136 ± 0.019	10	1.031 ± 0.025	10	1.140 ± 0.048

Variation in egg shape of oviposited clutches.—About half of the oviposited clutches contained neither pointed nor weakly pointed eggs. The maximum number of eggs in a clutch that was clearly peaked or weakly peaked was three while that of clearly peaked eggs was two (Table 2). Most of these peaked eggs appeared to be positioned at the anterior or posterior edge of the egg row.

TABLE 2. Frequency of oviposited clutches with peaked eggs in *Trimeresurus flavoviridis.*

No. of peaked eggs		Clutch	
Not-clearly peaked	Clearly peaked	Number	Proportion
0	0	43	0.45
1	0	11	0.12
2	0	8	0.08
3	0	3	0.03
0	1	12	0.13
1	1	10	0.10
0	2	4	0.04
1	2	5	0.05
Total		96	1.00

Variation in egg shape of partially oviposited clutches.—Ten females died with one or two oviductal eggs two or more days after oviposition. The mass and length of the most anterior oviductal egg were larger than those of oviposited eggs, and the relative mass of the former was larger than that of the most anterior egg in pre-ovipositional clutches (Table 1).

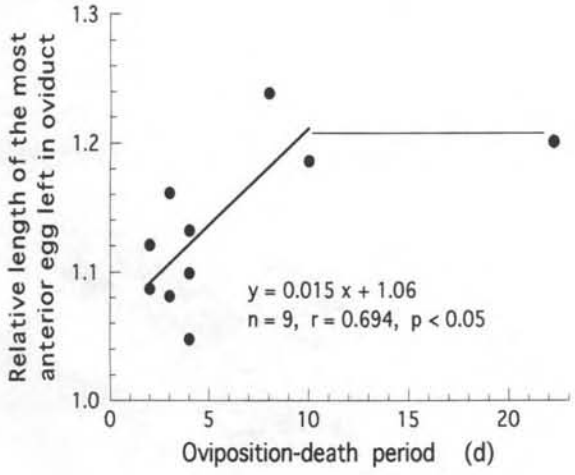

FIG. 1. Period from oviposition to death and the relative length of the most anterior egg remaining in the oviduct in *Trimeresurus flavoviridis.* The length of the most anterior egg was divided by the mean length of oviposited eggs in each clutch to determine the relative length of the most anterior egg.

The period (days) from oviposition to death was positively correlated with the relative length of the most anterior egg remaining in the oviduct (Fig. 1), especially in the 2–10 day period (Fig. 1, N = 9, R = 0.694, P < 0.05), but was not correlated with the relative egg mass (N = 10, R = 0.080). Therefore, at least for the most anterior egg remaining in the oviduct, the length may increase by about 10% in 10 days. On the other hand, female SVL was negatively correlated with the relative width of the eggs (N = 10, R = -0.767, P < 0.01). A significant increase in egg mass of the slender shaped eggs oviposited by small females (Ford and Seigel 1989; Nishimura 1983) was attributed to an increase in egg width.

My results indicate that in *Trimeresurus flavoviridis*, the volume of the abdominal cavity and other eggs may restrict the growth of oviductal eggs and cause shape modification in some anterior and posterior eggs within a clutch.

Acknowledgments.—I thank the many persons who collected snakes for me, Takao Kamura for keeping the snakes, and Akira Mori and anonymous reviewers for improving the manuscript.

Lepidophyma tarascae was described by Bezy et al. (1982) on the basis of three specimens from "near Mexiquillo, Aquila District, Michoacán, México." This locality is on the coast of Michoacán, ca. 16 km (by Hwy 200) WNW Caleta de Campos at 18°08'N, 102°56'W, but was listed inadvertently as 18°08'N, 103°56'W in the original description. Our observations indicate that the vegetation near Mexiquillo consists of degraded "Bosque Tropical Caducifolio" (Rzedowski 1978), whereas Alvarez and Diaz-Pardo (1983:143) list the type specimens as having been collected in "encinar." Moreover, field work conducted by the authors in the vicinity of Mexiquillo has failed to produce additional specimens of the species. A special effort was made to search rocky habitats similar to that mentioned in the original description. As members of the genus can be extraordinarily difficult to collect, additional work is necessary to establish definitively whether *L. tarascae* actually occurs at Mexiquillo, or whether the designated type locality may have been in error.

Recent field work, however, has established the presence of *Lepidophyma tarascae* in the northern sector of the Sierra de Coalcomán. A specimen (MZFC 8603) was collected in a cave (Cueva de la Virgen) on the canyon of the Rio Chilitos (18°52'N and 102°50'W) in the municipality of Aguililla, Michoacán. This is ca. 65 km N of the designated type locality and places the species near the Balsas Basin. The Coalcomán locality lies at 1225 m elevation in a transition zone between tropical deciduous forest and oak woodland, conforming closer with the vegetation reported by Alvarez and Diaz-Pardo (1983:143) for the type series.

The specimen from the Sierra de Coalcomán differs somewhat in morphology from the type series of *Lepidophyma tarascae*. It has slightly fewer total femoral pores (14 vs. 16–18) and gulars (40 vs. 41–43) and more dorsal scales (159 vs. 145–150). It shares with the type series the presence (on each side of the neck) of an uninterrupted longitudinal row of enlarged tubercles extending from the posteroventral margin of the tympanum to above the gular fold (Fig. 3 in Bezy et al. 1982), a feature that was utilized by Bezy and Camarillo (1995) to identify *L. tarascae* in their key to the xantusiids of Mexico. However, in the Coalcomán specimen this post-tympanic row of tubercles is not as distinct, i.e., it is less clearly separated from the scattered enlarged tubercles of the upper nuchal area than it is in the type series, approaching the condition observed in some *L. smithii* from Chiapas (e.g., MVZ 191448–49). The Coalcomán specimen lacks another distinctive feature found in the type series of *L. tarascae*. It has three dorsal interwhorls separating the enlarged caudal whorls throughout the length of the tail, whereas in the type series there are two in most of the proximal caudal segments (but three distally).

As is often the case with *Lepidophyma*, species decisions must contend with limited sample sizes, discordant morphological variation, and geographically disjunct populations (Bezy 1984). Although the Coalcomán specimen differs somewhat from the other three known specimens of *L. tarascae* we provisionally assign it to that species. The four specimens thus assigned to *L. tarascae* have fewer total femoral pores (14–18) than all other members of the genus except *L. dontomasi*, *L. occulor*, and *L. smithii*. From these *L. tarascae* differs most markedly from *L. dontomasi* in having strongly enlarged lateral tubercle rows. In some morphological features the Coalcomán specimen bridges the morphological gap between *L. tarascae* and *L. smithii*. However, we retain *L. tarascae* as a separate species as all four known specimens differ from *L. smithii* (302 specimens examined) and *L. occulor* (11 examined) in having fewer than 162 dorsal scales and fewer than 44 gulars.

Acknowledgments.—We thank H. W. Greene (MVZ) for making specimens available for study, Francisco Vargas Santa Maria for assistance with the field work, and Kathryn Bolles, Lee Fitzgerald, and an anonymous reviewer for critical review of a previous version of the manuscript. The Circular Aesculepian Temple (Tholos) at Epidauros, Greece: An Early Snake Pit?

BAYARD H. BRATTSTROM
Department of Biological Science
California State University, Fullerton, P.O. Box 6850
Fullerton, California 92634-6850, USA

There were only a few circular temples (Tholos) built in ancient Greek times. The rotunda temples at Olympia and Delphi are probably the most famous and definitely the most complete although there is another in the market place at Athens. In the theater, sports, and healing complex at Epidauros, Greece, there is a unique Tholos designed or built, as were the others, by Polycleitus the Younger or his students between 360 and 320 BC. There is nothing left of this temple, which was located just west of the Temple of Asklepios, except for the foundation. Several portions of the tile floor, portions of the roof and two circles of columns from the temple are now in the museum at Epidauros. The Tholos had an external doric and an internal free standing corinthian colonade (Berve and Gruben 1962; Brilliant 1972; Dinsmoor et al. 1973; Lawrence 1957). The temple was unique, not only among circular temples, but apparently among most Greek temples in that it had a subterranean pit, cellar, or basement under the temple (Figs. 1–2). In addition, the floor of the temple had a large central circular opening. Below the floor, the underground portion of the temple consisted of a labyrinth of three circular walls, each within the other. The walls were separated enough for a small passage between them and the passageways were linked by breaks or half walls within each of the circular walls. Each of these little doorways to the next inner passageway was located at a different position in each wall. Whether or not there was a covering for the opening in the middle of the temple and whether there were stairs descending into the subterranean passages is uncertain.

Though unique, the purpose or function of the rotunda and its subterranean circular passageways, in spite of much speculation, is still unknown. An inscription, which recorded the accounts of monies received and spent on the building, called it the Thymela (place of sacrifice; Lawrence 1957). Many (Berve and Gruben 1962; Pillement 1973) have suggested that holy snakes of the healing god Askelepios were kept there. The circumstantial evidence for this suggestion included the fact that this was a sports, gymnasium, bath, and healing center and that the god Askelepios (son of Apollo) had a temple at Epidauros as did his daughter Hygieia, goddess of health. The Physician Hippocrates (450–370 BC) visited Epidauros and there was a festival called "Hippocrates Day" or the "Festival of the Receiving of the Staff" (Berve and Gruben 1962). The staff was, of course, the Asclepian staff with a single (and later two) coiled snakes that has been the symbol of the medical profession for centuries. The first portrayal of the snake on a staff is probably from 1100 BC and snakes may have had an association with curing peoples' ills in Mesopotamia in the 2600s BC (Gimbutas 1982; Laughlin 1962; Schouten 1967). There is, of course, a real, living snake called the Asclepian (Aesculapian) snake (*Elaphe longissima*), and snakes have long been associated with good or evil in many different human cultures.

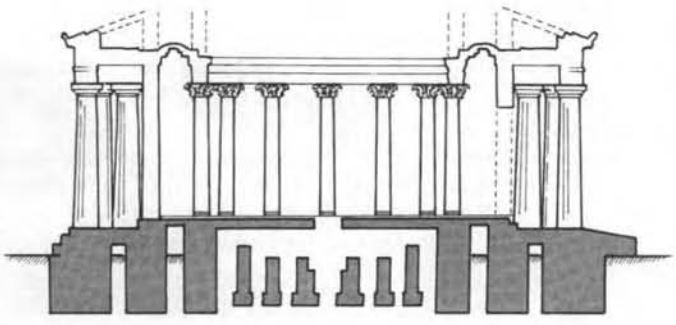

FIG. 1. Diagram of the Tholos at Epidauros, Greece showing location of subterranean area which may have been a snake pit. Modified from several sources, especially Berve and Gruben (1962), and personal observation.

As a herpetologist and a naive tourist at Epidauros, I asked myself this question; Was the Tholos at Epidauros a snake pit? Considering the biology of the Asclepian snake, the climate of Greece, and the nature of the Epidaurian complex, I propose that the subterranean portions of the Tholos was, in fact, one of the earliest known snake pits.

Temperature Regulation of Snakes

Many lizards, such as the common European wall lizard (*Lacerta* sp.), seen crawling over the Grecian ruins today, bask in the sun and have high body temperatures. While they do bask in the sun on cool spring days, most snakes have lower preferred body temperatures than most lizards (Brattstrom 1965). Snakes seldom have body temperatures above 30°C. Because snakes are limited by both high and low temperatures, the yearly activity cycle of snakes corresponds to the prevailing temperature changes in an area. Most snakes in southern Europe emerge from underground retreats in March and April, engage in some basking behavior on cool mornings, feed, and mate. As the spring turns into summer the snakes become increasingly nocturnal in their activity (Brattstrom 1965). By mid-summer through early fall it is usually so hot in Mediterranean climes that snakes spend this period in activity in underground retreats. In mid-summer even the wall lizard is active only in the early morning and late afternoon (pers. obs.). There may be a period in the late fall when the temperature again allows the snakes to be active. As winter begins and the temperatures drop, the snakes again become inactive and retreat to subterranean retreats to avoid the cold. Thus, the snakes avoid the summer's heat and the winter's cold in inactivity and torpor. The subterranean basement of the Tholos at Epidauros would have been an excellent place to store snakes from both the heat and the cold. Such cellars, like caves at that latitude, maintain a constant temperature that is the average temperature of the area. Hence, both the summer and winter temperature of the underground portion of the Tholos would be, estimated on the basis of latitude, about 15–20°C.

Keeping Snakes: Snake Parks and Pits

Snakes have long been associated with good or evil (Gimbutas 1982). They are seldom portrayed as neutral. Snakes have been associated with power, healing, or other beneficial traits (as in keeping pestilence down by consuming rats and mice). Associations of snakes and good health go back to Mesopotamian times and snakes played an important role in Egyptian mythology. A natural evolution of this interest in snakes would be the keeping of colonies of snakes. The Hopi Indians of the American South-

FIG. 2. Photograph of the three-walled subterranean basement at Epidauros. This is all that remains on the site. Portions of the temple are preserved in a nearby museum. (Photo by P. Murphy)

west, for example, collect gopher snakes and rattlesnakes and keep them for weeks prior to harvest snake dances, at which time they are released. Today, snakes are kept for a variety of reasons, ranging from entertainment and education to venom collection and religious ceremonies. In addition to reptiles in zoos in the United States, we find numerous road-side snake pits, snake farms, reptile gardens, and serpentaria. Others occur in South Africa, Australia, Japan, China, Thailand, Brazil, and Mexico. Snakes are also kept for religious purposes in Hindu temples in India (especially associated with Kali cults) and by Christian "snake cults" in the American Appalachian region. It is not, therefore, out of line to think that Epidaurians might have also kept snakes. Indeed, there may have been snake pits in the stoa of the Asclepieum at Athens and in the Erechtheum (Dinsmoor et al. 1973).

Snakes at Epidauros

Biological and cultural evidence, along with the circumstantial evidence of Hippocrates, Asklepios, the snake staff, the healing environment of Epidauros, and the fact that many cultures have kept large numbers of snakes for many reasons, suggest that the subterranean basement of the Tholos at Epidauros would be an excellent place to keep snakes. Clearly, it is conjecture whether snakes were passed up through the floor by some important person, or deposited down into the hole in the floor of the Temple by worshippers or those wanting to be cured of an affliction. I only want to suggest that the function of the basement of the Tholos at Epidauros was for holding snakes, and indeed, may have been one of the first snake pits. At the least, I encourage others who might explore archaeological or historical evidence to consider this hypothesis and search for other evidence to support or disprove the hypothesis.

Reticulate Melanism in Southwestern Populations of *Chrysemys picta bellii* (Testudines: Emydidae)

JAMES N. STUART

Museum of Southwestern Biology, University of New Mexico
Albuquerque, New Mexico 87131-1091, USA
e-mail: StuartJN@unm.edu

The western painted turtle (*Chrysemys picta bellii*) ranges from the Great Lakes region and central Mississippi Valley westward to the Pacific coast, with disjunct populations occurring in the southwestern United States and northern Mexico (Stebbins 1985). Among specimens of *C. p. bellii* from North Dakota, Smith et al. (1969) discovered an unusual color pattern which they termed "reticulate melanism." This condition, typified by a net-like arrangement of dark lines overlaying the normal carapacial pattern, was documented subsequently in other *C. p. bellii* populations in Minnesota and southern Canada (Ernst and Ernst 1973; MacCulloch 1981; Schueler 1983). Based on reported localities of occurrence, Lovich et al. (1990) and Ernst et al. (1994) considered this melanistic pattern to be limited to northern populations of *C. p. bellii*. This note documents the prevalence and characteristics of reticulate melanism in southwestern populations of this turtle.

Methods.—I defined reticulate melanism (RM) based on descriptions and illustrations provided by Smith et al. (1969) and Schueler (1983). Schueler (1983) observed that Canadian *C. p. bellii* with carapacial RM also typically exhibit a parallel condition in which the longitudinal stripes on the top of the head are either obscured or disrupted by a dark reticulate or vermiculate pattern. My preliminary observations indicated that this cephalic pattern develops earlier than carapacial RM in maturing males, and Schueler (1983) found it in all males with well-developed carapacial RM. Because of its similarity to and apparent correlation with carapacial RM development, the reticulate head pattern was considered a component of RM in this study.

I examined preserved specimens of sexually mature *C. p. bellii* from three drainage systems in New Mexico (Rio Grande, Pecos River, and San Juan River) where native populations occur (Degenhardt et al. 1996). Specimens are deposited in the University of New Mexico Museum of Southwestern Biology (MSB). Straight-line plastron length (PL; to nearest mm) and sex were recorded for each specimen. Males were considered sexually mature based on the presence of secondary sexual characteristics (elongated foreclaws and thickened tail base); females ≥ 130 mm PL were considered sexually mature (Christiansen and Moll 1973). Based on my preliminary observations and those of Schueler (1983), RM progresses with maturation from the anterior part of

the body (top of head first, then the anterior laminae of the carapace) to the posterior part of the carapace. To quantify this progression, specimens were categorized into five stages: Stage 0—no cephalic or carapacial RM; Stage 1—early development of cephalic RM only; Stage 2—well-developed cephalic RM only; Stage 3—cephalic RM, plus RM on anterior 25% of carapace; Stage 4—cephalic RM, plus RM on ≥ 50% of carapace. RM stage and PL were compared using Spearman's correlation coefficient. Other characteristics of RM development were evaluated qualitatively using museum specimens and a sample of ca. 50 live *C. p. bellii* captured in the Rio Grande in 1995–96.

Results.—A total of 268 preserved adult *C. p. bellii* (159 males, 109 females) were examined. Males in the sample were 74–167 mm (117.3 ± 1.4 SE) and females were 130–202 mm (147.8 ± 1.4 SE). Data for RM development in males are presented in Table 1 and Figure 1. All females were categorized as Stage 0. The supraocular and medial head stripes in nine females (132–194 mm PL) were slightly mottled, but in no case did the cephalic pattern approach the distinct stripe modifications seen in melanistic males. No female possessed a shell pattern resembling that of males with carapacial RM.

RM stage was positively correlated with plastron length in males ($r = 0.77$, $P < 0.01$). Males with no RM (Stage 0), cephalic RM (Stages 1–2), and both cephalic and carapacial RM (Stages 3–4) comprised 35.8%, 34.0%, and 30.2% of the sample, respectively (Table 1). The majority (76.1%) of males examined were from the Rio Grande drainage, therefore geographic variation among the three river systems was not compared statistically. However, the occurrence of RM in the small subsamples from the Pecos and San Juan rivers appeared to follow the pattern of development seen in the Rio Grande population. Carapacial RM was typically darkest and most contrasting in those individuals with the most extensive development of this shell pattern. In addition, cephalic RM was usually most pronounced in the largest individuals with extensive carapacial RM. The cephalic pattern was essentially restricted to that part of the skin which overlays the prefrontal, frontal, and parietal bones of the skull; disruption of the head and neck stripes beyond this limited area was observed in ca. 30% of males (Stages 3–4) where it was very slight. The ventral surface of the body was unaffected by RM in virtually all specimens examined, although one Stage 4 male had an extensively-spotted plastral pattern.

TABLE 1. Summary data for straight-line plastron lengths (PL, in mm) of 159 adult male *Chrysemys picta bellii* from New Mexico, grouped by reticulate melanism (RM) developmental stage (0–4). See text for explanation of RM stages.

RM Stage	N (% total)	PL Mean ± SE (Range)
0	57 (35.8)	101.7 ± 1.7 (74–135)
1	26 (16.4)	114.4 ± 2.4 (93–139)
2	28 (17.6)	124.1 ± 2.7 (84–155)
3	7 (4.4)	132.9 ± 3.5 (122–149)
4	41 (25.8)	133.6 ± 1.7 (114–167)

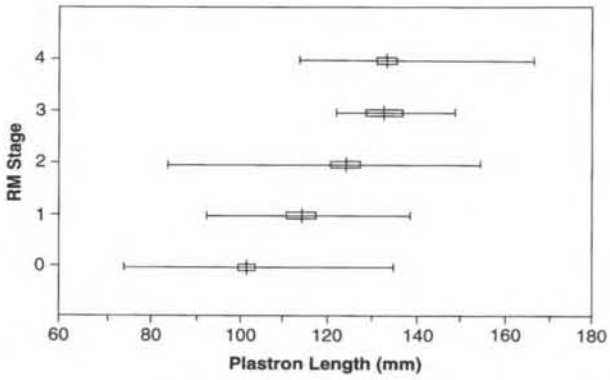

FIG. 1. The relationship between straight-line plastron length (PL, in mm) and reticulate melanism (RM) developmental stage (0–4) in 159 adult male *Chrysemys picta bellii* from New Mexico. Box plots of PL include mean, one standard error, and range (from Table 1). See text for explanation of RM stages.

Two other features possibly connected to RM development were noted but not quantified in this study. Based on examination of museum specimens and live males with Stage 4 RM from the Rio Grande, individuals with well-developed carapacial RM (70–100% of carapacial surface affected) often had overall darker carapaces than females and Stage 0 males. In addition, the junctions between the nuchal and first marginals of most specimens at Stages 3–4 were often sharply indented, producing a serrated or "sawtooth" appearance to the anterior edge of the carapace (visible in photographs in Smith et al. 1969:174, and Schueler 1983:83). Both of these features were much less frequently observed in mature females and were rarely seen in Stage 0 males.

Discussion.—The results of this study closely parallel those of Schueler (1983) for Canadian *C. p. bellii*; he noted that all large (> 150 mm PL) males were melanistic. In this study, all males > 135 mm had cephalic RM and all males > 155 mm had carapacial RM in addition to the cephalic pattern. It is noteworthy, however, that in few examined specimens was the carapacial reticulum as dark and continuous as in the example illustrated by Ernst et al. (1994:282); a narrow vermiculate or broken reticulate pattern was more typical of fully melanistic *C. p. bellii* from New Mexico.

It is unclear if the serrated anterior marginals and overall darker carapace of melanistic males is connected to RM development. These features may actually be secondary characteristics of maturity rather than components of RM as they are also present in some large females. The underlying cause for development of the anterior carapacial serration is apparently unknown.

Although the causes and characteristics of male melanism have been partially elucidated in other emydid turtles (e.g., *Trachemys* spp.), data for *C. p. bellii* are relatively limited and, in some cases, conflicting. Previous studies indicated that RM was restricted to northern populations of *C. p. bellii* (probably due to an absence of studies elsewhere). However, the commonness of this pattern in New Mexico, near the southern distributional limit of the subspecies, indicates that its occurrence is not influenced by latitude. Data presented in MacCulloch (1981), Schueler (1983), and this study demonstrate that RM is limited to males, although Ernst and Ernst (1973) reported that females also may exhibit this pattern. Ward (1984) stated that only females in *C. picta* are melanistic, but it is unclear as to what form of melanism or to which

subspecies he was referring. Apparently, androgens are involved in the development of melanism in males of some *Trachemys* spp. (e.g., Garstka et al. 1991), but their role in RM development in *C. p. bellii* is unknown (Lovich et al. 1990). Unlike male melanism in some *Trachemys scripta*, which involves disruption and reorganization of the pattern on almost all surfaces of the skin and shell (Lovich et al. 1990), RM in *C. p. bellii* is restricted to the carapace and top of the head. Restriction of this form of melanism to dorsal surfaces underlaid with bone suggests that its location on the body may be influenced by: 1) thickness of soft tissue; and 2) exposure of the surface to sunlight during basking. Additional studies are needed to clarify the geographic distribution of RM in *C. p. bellii* and investigate the possible roles of sex hormones and ultraviolet radiation exposure in its development.

Acknowledgments.—I thank P. Stone, C. Painter, J. Miyashiro, H. Smith, W. Degenhardt, B. Dennis, and an anonymous reviewer for comments and assistance; and H. Snell and D. Sias for facilitating use of MSB specimens. I also acknowledge the contribution of J. Christiansen, whose past collecting efforts in New Mexico added greatly to this study.

Continued reports of amphibian declines from around the world (e.g., Drost and Fellers 1996; Green 1997; Kuzmin 1994; Joglar and Burrowes 1996; Pechmann et al. 1991; White 1995) dictate that amphibian mass mortalities be reported (e.g., Blaustein et al. 1995; Márquez et al. 1995), and their causes be determined, where this is possible. Here, we describe the circumstances of an apparently natural mass mortality of green frogs (*Rana clamitans melanota*).

On 10, 11, and16 May 1996, we collected 23 adult ranid carcasses adjacent to a small, seasonal wetland, dominated by sedges (*Carex* sp.), located at T35N, R17W, in Polk County (section 29), Wisconsin, USA. Carcasses were placed in the sun to evaporate surface moisture, and stored in individual zip-lock bags. Additional preservation was not necessary, animals remain today as they were when discovered. Exceptions are the few animals that developed surface fungus; these were rinsed with 70% ethanol. Twelve frogs have been deposited in the Michigan State Museum (Herpetological Skeletal Collection 4444–4455), eleven in the Milwaukee Public Museum (30251–30261). Because animals were similarly sized (see below) and clustered, they were assumed to be a single species. One carcass was sent to J.A.H. for identification using ilial morphology (Holman 1984, 1995). Age estimations based on skeletochronological methods were conducted (N = 19). To observe lines of arrested growth (lag lines), the central portion of one of the femurs of each carcass was embedded in paraffin according to standard histological techniques (Kiernan 1990), and sectioned at 12 µm. Body measurements (total length), the presence of eggs, and the number of femoral lag lines were determined. Lag lines within the bone were counted. To this total an additional line was added marking the winter of 1995–1996 (for a similar assumption see Acker et al. 1986).

All carcasses were desiccated, blackened, leathery (Fig. 1), and entangled in detritus near the wetland edge. Carcasses were not pliable, joints were rigid. There was no evidence of insect larvae within the carcasses. Adipocere was not present. At the time the dead frogs were collected the water was out of its banks; the water's edge was in the lawn of the owners, and the deepest portion of the wetland was about one half meter. This wetland usually dries by late summer and remains dry through the winter; 1995 was unusual in that the wetland refilled prior to freeze-up. The dead frogs were found in two areas just above the waterline along the shallow northeastern side of the basin. Most skeletons

were intact, held together by skin, ligaments, and desiccated muscles and tendons; bones were clearly visible (Fig. 1). Eggs in gravid females were conspicuous (Fig. 1). Of the 23 frogs collected, 8 were gravid females. Seven of these females were intact, the remaining female consisted of a set of ovaries found dried together with a partially disarticulated skeleton of what appeared to be a single frog (no duplicated limbs or vertebral columns).

Based on ilial morphology (Holman 1984, 1995) these frogs were identified as *Rana clamitans*. Our skeletochronological analysis supported this identification in that lag line morphology did not resemble the tight rings illustrated for northern leopard frogs (*Rana pipiens*; LeClair and Castanet 1987). Green frogs are probably the most common ranid species in Wisconsin, occurring in every county (Casper 1996).

Because most green frogs inhabiting these northern latitudes overwinter as Gosner (1960) stage 25 (i.e., legless) tadpoles (Vogt 1981) an additional year was added to our age estimates. (We note that several features of green frog life history, including a long breeding season [Minton 1972; Vogt 1981; Wells 1977], the potential for double clutching [Wells 1976], and tadpoles that may or may not overwinter, produce a variability in this species that mitigates against confidence in calculating a-posteriori age assessments.) Based on lag line counts and the presence of eggs in some individuals, our animals were young adults. Age estimates indicate that 15 of 19 animals were two and one-half years old, two were one and one-half years old, two were three and one-half years old. Wells (1977) reported that both sexes usually reach sexual maturity in the year following metamorphosis (i.e., about two and one-half years) although some may postpone breeding until the following year. Martof (1956) indicated that green frogs in natural populations probably live at least five years. Our green frog carcasses ranged in size from 60–80 mm. These animals were small compared with reports from other studies (Minton 1972: males 60–84.5 mm, females 64–88 mm; Vogt 1981: 60–90 mm; Walker 1946: males 69–90 mm, females 72–92 mm; Wells 1977: males 90–103 mm, females 98–105 mm). These size differences may be due in part to artifact; desiccation shrinks overall body length (Spindler 1994). Even so, these frogs were large enough to be breeding animals. Green frog males are sexually mature at 60–65 mm (Martof 1956; Ryan 1953). The smallest male Wells (1977) found calling was 63 mm, the smallest female that laid eggs was 71 mm. By comparison, Wells (1977) reported that newly metamorphosed animals range in size from 28 to 38 mm.

The winter of 1995–1996 was severe in the Upper Midwest. The National Weather Service station in Amery, Wisconsin, the nearest weather station (located about 29 km southeast of the site), reported that snowcover was continuous from November 26 to April 10—137 days (U.S. Department of Commerce, National Oceanographic Administration, National Weather Service). The deepest snowcover, 40 cm, occurred on March 25–27. During this time of snowcover the average daily maximum air temperature was -4.1°C and the average daily minimum was -12°C; both maximum and minimum temperatures were 2°C below the 1930–1950 annual average. One local fisherman claims that there were 125 cm (41 inches) of ice on the nearby lakes. Lakes and wetlands stayed frozen until the spring melt. Several fish winterkills in the region were reported to the Wisconsin Department of Natural Resources office in nearby Cumberland. A shallow portion of the adjacent Little Butternut Lake experienced a fish kill.

Almost certainly the cause of the death of the green frogs described here is winterkill, possibly a result of a poor hibernating site choice during an abnormally high water period. Green frogs usually hibernate in permanent waters (Harding 1997; Oldfield and Moriarty 1994). If death had occurred during the previous summer or fall, evidence of decomposition or ingestion by insect larvae should have been apparent. In our experience in the Upper Midwest, warm weather mass mortalities are usually associated with drying conditions or disease and affect aquatic larval stages. Dry conditions were not a factor in producing the deaths of our animals. These adult frogs were found in vegetation within 25 m of Little Butternut Lake; in fact, one group of frogs was found closer to the lake than to the opposite side of their wetland. We can envision no warm weather scenarios under mesic conditions that could plausibly create a mass mortality of apparently healthy green frog adults and produce clusters of carcasses that show little evidence of decomposition or scavenging.

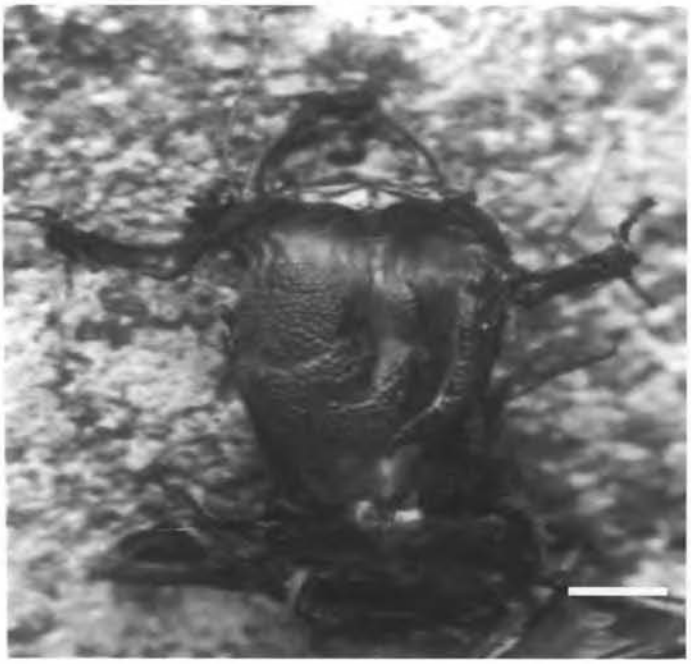

FIG. 1. Ventral view of mummified gravid female green frog (*Rana clamitans melanota*). Note darkened, desiccated body and distinct skeletal features. While most of the viscera have shrunken, the ovaries and individual ova can be distinguished. Scale bar = 1 cm.

In the usual sense, winterkills occur in water, most frequently in basins that are shallow (shallow water restricts dissolved oxygen availability) and during winters when snowfall is high (deep snow restricts sunlight penetration and therefore photosynthesis; see Lannoo 1998). Aquatic winterkills have been reported previously for amphibians (Bradford 1983; Corn and Fogleman 1984; Manion and Cory 1952) and in some areas may be a common cause of mortality (Barica and Mathias 1979; Lannoo 1996; M. Redmer, pers. comm.). Three facts, however, suggest that aquatic winterkill was not the cause of death in these animals. First, all carcasses were found above the water level of the wetland, which admittedly could have lost water since its spring melt. Secondly, in our experience spring melt following a winterkill can create an olfactory experience not soon forgotten for those living downwind. But immediately following ice off, the wetland did not reek of methane, hydrogen sulfide, or other byproducts of anaerobic decomposition; nor did it smell of aerobic decomposition. Thirdly,

and most convincing to us, the lack of decomposition suggests that the time from death to mummification could have been, at most, six months (mid-October 1995–mid-April 1996, see below), which seems to be a time course too rapid for animals to mummify while embedded in ice.

Thus, a terrestrial winterkill scenario is most likely. These animals appear to have been trapped out of the water. After death but before decomposition, carcasses were frozen and covered with snow, which dehydrated and preserved them. In general, mummification is a common process, and mummified frogs have been produced following exposure to phosphoric acid in France (Weigelt 1989). However, authoritative books on the subject of taphonomy (Behrensmeyer and Hill 1980; Weigelt 1989) do not address mummification following aquatic winterkills. Weigelt (1989) reports that mummification can take place anytime a carcass loses most of its water content before decomposition begins. Under freezing conditions, water loss occurs through sublimation. Rapid sublimation is known to occur in dry snow, as has been proposed for the preservation of the Hauslabjoch "ice man" (Spindler 1994). This process of sublimation in snow cover produces a natural form of freeze-drying, and seems to be a more likely explanation than preservation in ice for the presence of the mummified carcasses we discovered.

We close with an encouragement to report mass mortality events. Such accounts would allow a better assessment of the relationships between amphibians and the environmental conditions they experience.

Acknowledgments.—We thank Ray and Alma Johnson for access to their wetland; Dee Nali for discovering the first frog carcass; Dave Evenson, Wisconsin Department of Natural Resources, Cumberland, for a consultation about winterkills; and Keith Zygowicz of the Polk County Agricultural Soil Conservation Service, for providing the weather data. Thanks to Mike Redmer and to Mike Conley for their reports of other mummified frog examples. Thanks also to Richard Wassersug and Joe Eastman for consultations on possible causes underlying natural mummification in wintertime aquatic systems.

A Profile of Zoo Herpetologists

The following account is based on our impressions of valued colleagues in zoos, refined over many years of friendship and interactions with them. Many of these exhibited characteristics could be applied to herpetologists in other settings as well. A number of zoo herpetologists developed their interest in amphibians and reptiles as youngsters. As their interest expanded, many maintained large living collections, especially snakes. It was not easy to like snakes because most people, including parents, viewed these creatures with loathing and disgust. Consequently, the young enthusiast had to continually defend his or her interest as being acceptable in polite society. Since the young herpetologist was generally on the defensive, the possibility of developing argumentative, antisocial and aggressive patterns in response to criticism was real indeed. An interest became an obsession and social interactions with non-herpetologists became less frequent. In later years, marital relationships, especially when the partner was not interested in herpetology, could be strained beyond repair. A number of our colleagues have had multiple marriages. One zoo herpetologist was separated from his second wife. He was offered a curatorial job in another city which was accepted but his wife remained behind. After several years in his new post, he was asked about his unsatisfactory relationship with her. He was unable to remember his wife's first name even though they were still legally married. He pointed out that if he were to face death unless he remembered, he would die!

If the zoo herpetologist had an interest in collecting organisms other than amphibians and reptiles, there were parallel patterns in these collections as well. Those interested in plants tended to collect certain groups: cacti, succulents, cycads, bromeliads, and carnivorous plants. Be it invertebrate, fish, bird, or mammal, there was one consistent theme characterizing a zoo herpetologist's collection: carnivory! If invertebrates were collected, they were often spiders, scorpions, or predatory insects. Living fish collections included catfish, primitive fishes such as elasmobranchs, gar, bircher, lungfish, and predaceous fishes. When birds were kept, they were most often raptors. A mammal collection reflected similar specialization: small exotic carnivores.

Since most of our colleagues throughout the years have been male, opportunities for women being limited, our analyses are based on behavior of men in herpetology. It is refreshing to see women entering the zoo profession in increasing numbers and it will be interesting to try to analyze their behavior in the future. Clearly not all men in the profession reflect all of these patterns but the following list may help define the zoo herpetologist:

—Academic careers often are less than stellar. This may be due to a lack of interest in coursework not directly related to herpetology.

—Friendships are mostly limited to other herpetologists.

—There is a measure of uncertainty among zoo herpetologists in that they are not certain whether they should view themselves as professional herpetologists or herpetoculturists. In reality, they are a blend of the two disciplines. Zoo herpetologists must consider theoretical issues in biology but use applied methods to maintain living collections.

—One does not enter the zoo field to make money. When discretionary income is available, it is often spent on herpetological literature or field trips.

—Living collections of amphibians and reptiles are often maintained at home as well as at the zoo. There is a trend to maintain exotic rather than domestic animals. A propensity for herps may happen because they are generally small and easily accommodated. If one were interested in mammals, it would not be easy to keep a hippopotamus in the back yard. The types of wild creatures kept by zoo herpetologists are usually not responsive to human interaction but rather are likely to be highly defensive or independent of any human activity. Hence, any animal that responds positively to a human advance is generally considered to be undesirable. This is different from many other zoo workers who seem to derive pleasure from bonding with animals in a personal way. Should a favorite animal expire, it can be a highly traumatic event. There may be a reason for this difference. Zoo herpetologists view their animals as individual members of a species group which are integral parts of a complex ecosystem. Life and death are part of the natural mosaic so the loss of any one amphibian or reptile is viewed as inevitable and not particularly troubling, especially since a strong personal bond has not been created. Frustration often stems from the loss of an important specimen in a breeding program which may be irreplaceable, with conservation implications. Unlike workers in other animal departments in the zoo, herpetologists almost always use technical names for their charges and almost never use a pet name.

We do not wish to offend any of our non-herp zoo colleagues who wish to bond with their animals but there is an inherent danger to this approach. First, animals should imprint on conspecifics rather than humans. Second, zoo visitors receive the wrong message. Animals should be viewed not as individual entities dependent on humans per se but rather as part of a larger group with selection pressures shaping this taxonomic unit. In other words, individual animals live and die in the wild but are part of a broader species and community assemblage. The zoo visitor needs to be shown that zoo workers are aware of the distinction between individual and group and that zoo professionals are making every effort to maintain captive animals in as wild a state as possible with minimal human interference and interaction. With this approach, thorny issues such as euthanasia and culling of *individual* specimens inappropriate for breeding programs can be addressed. Some zoo workers invest considerable time and money to save an individual animal through such protocols as elaborate veterinary procedures or hand rearing neonates which are possibly inferior and lack fitness. These resources could be directed in more positive directions.

—Priorities may be skewed. One keeper had an extensive array of terrariums arranged throughout his living room but there was virtually no furniture. His wife complained bitterly that all he cared about were his reptiles. She underscored her argument by pointing out that he took food from their baby's mouth in order to have the money necessary to buy mice to feed his snakes.

—Career advancement in the zoo field beyond herpetology is not a high priority. There are a few exceptions to this trend: Carl Kauffeld, late Director of the Staten Island Zoo; John Werler, re-

tired Director of the Houston Zoo; and Roger Conant, retired Director of the Philadelphia Zoo serve as examples, disproving the general rule.

—There are two distinct modes of dress. One group, certainly in the minority, dresses in sartorial splendor with nicely pressed and laundered clothes. The second group appears to have found mismatched clothing at a garage sale. These items seem to be infrequently washed and never ironed. A supervisor at a midwestern zoo regularly wore a beanie with a propeller attached. One male zoo herpetologist, apprehensive and anxiety-ridden, was preparing for an eagerly expected date with a winsome young lass. His personal habits were not exemplary for he rarely cleaned his clothes. He threw his soiled garments into a pile roughly waist-high which could accurately be visualized as a steaming compost pile. As he was sorting through this unmentionable heap to locate the least offensive article of clothing to wear on his date, he discovered a large, dried pizza.

—Many of our colleagues reflect vigorous heterosexual behavior with little evidence of success in the game of love. As stated earlier, there were few women in the profession in the early days. At the herpetological conferences, those beleaguered women were the center of attention. It was a situation remindful of the spring emergence of red-sided garter snakes in Manitoba, Canada where scores of male snakes pursue females. At these conferences, female mate choice was operative.

—For male zoo workers, there has been a trend toward permanent facial hair even during those periods in the United States when grooming styles were less hirsute.

—Dining habits tend to reflect a high degree of carnivory with food consumed in impressive quantities. In at least two instances, keepers ate mice and grubs to shock zoo visitors who disliked snakes. Occasionally, culinary habits were questionable. One keeper's residence was so overrun with cockroaches that they marched in phalanxes at night. The butter dish was always left on the kitchen sink at night rather than in the refrigerator to ensure that the butter was soft and could be easily spread on slices of bread each morning. As dawn approached, mummified roaches would be stuck in the butter in a scene remindful of the La Brea tar pits. As the keeper prepared his morning repast, he would scrape legs, wing covers, and antennae off the spread. Although he generously offered buttered toast to his house guests, the gift was never accepted.

—A number of our colleagues have had or currently have a motorcycle.

In summary, zoo herpetologists are generally highly focused, somewhat aggressive individuals who enjoy and nurture live animals but may not be as considerate toward their fellow man. They should feel lucky that they have been able to combine their interest with their profession.

Curators Versus Keepers

At the present time, the rights of zoo employees to work in a non-abusive environment are well protected legally and if their rights are trampled, legal options are available to redress grievances. Yet during the period between 1950–1975, employees might be subjected to unimaginable conditions by a few unreasonable curators. Several examples will serve to illustrate this point. A curator, after observing dirty waterbowls contaminated with fecal matter, demanded that all departmental employees drink from the vessels in order to learn proper sanitary procedures. In another instance, zoo keepers were taught how to fold a paper towel properly when cleaning animal enclosures and if the towels were not folded in an acceptable manner, keepers could suffer severe consequences, including suspension.

In some zoos, keepers were not allowed to feed their charges as these employees were regarded as incompetent by the curator. It was a privilege, reserved only for the curator, to feed these herpetological treasures. A curator who had told his people never to feed pink mice to a saw-scaled viper watched a keeper violate his instructions. He raced from the public area to the service section, reached into the enclosure and pulled the mouse from the snake's mouth. There would be no eating of prohibited substances in his domain! In response to this transgression, the curator forced this guilty keeper to scrub the floor of the entire rear service area with a toothbrush. Should a specimen expire of unexplained causes, some curators berated their keepers incessantly; employees might be punished for allowing the creature to die!

One woman keeper was carrying a large tray of rodent water bottles to a sink for cleaning. Unhappily, she lost her balance and fell amidst broken shards of glass whereupon she suffered lacerations. The curator, seeing her standing unsteadily in the doorway dripping blood, yelled and ran into the room past her. As she tried to reassure him that she was not severely injured, he ignored her and held the broken pieces in his hands, exclaiming that he had used those same bottles for many years and their loss was catastrophic; those bottles were irreplaceable!

Some keepers could truly test the patience of a curator. One was characterized by the curator as clumsy, scattered, and careless; an inordinate number of snakes under his care escaped. The curator, under strain from many administrative duties, engaged in a daily ritual to calm his shattered nerves. Every morning, he walked through the public area and inspected all of the enclosures. At the end of his tour, he would pause at the front of his favorite terrarium and visibly relax. This particular exhibit reflected his personal touch for he had landscaped the cage with an interesting variety of tropical plants and stocked it with beautiful Neotropical treefrogs. On one particularly stress-filled morning, he was startled to see a garter snake in his terrarium eating the last of his treefrogs. In a fury, he shouted for the hapless keeper to come immediately to see the carnage. His employee, busy at work in the rear section, heard his call and ran into the public area at full stride, whereupon he lost his balance, slid into the curator and upended him. The curator, by now completely out of control, rose to his feet, pulled the keeper off the floor by his hair, and repeatedly banged his head on the exhibit glass, all the while shouting how incompetent and stupid he was to allow such a fiasco to occur. The curator had to be restrained by fellow workers!

Although bushmasters were highly desired in zoo collections, they were delicate captives and little was known of their reproductive biology. This same curator had a particular fondness for bushmasters but his success rate with them was marginal. A potentially gravid female was imported and set up in isolation in the rear section. Each day, the curator would fantasize about beautiful baby bushmasters and stare into the cage to see if she had oviposited. One memorable day, she was coiled around a clutch of newly-laid eggs. All of the eggs were removed for artificial incubation. These were the primitive days before incubators and vermiculite were used to incubate reptile eggs so his plan was to create a suitable spot which offered appropriate heat and humidity. He chose a site that seemed to cover all requirements for humidity: a metal stock tank half-filled with water which housed a variety of small crocodilians and aquatic turtles. He placed a wooden plank on top of the tank and set the egg container on top.

For additional heat, a reflector and heat bulb were suspended from the ceiling above the eggs. His final task was the most important. A line was drawn on the floor around the tank. His nemesis, the now frog-less keeper, was not allowed to cross this line to view the eggs under any circumstance. It was inevitable that a disaster would occur. One day, when the curator was not at the zoo, the keeper noticed that the bulb was no longer burning. Rather than calling the curator at home, he chose to replace the bulb himself. As he stood on the plank to change the darkened bulb, he lost his balance and dumped all of the eggs into the tank whereupon crocodilians and turtles alike feasted on this unexpected fare. The keeper's life thereafter was exceedingly unpleasant.

Keepers occasionally were expected to work many additional hours over the normal 40-hour weekly complement without compensation. If they were unwilling, they were singled out as malingerers without a serious interest in herpetology and their professional commitment was questioned; in rare cases, curators physically attacked keepers when a dispute arose. Some institutions reflected a militaristic philosophy since keepers had to stand at attention for daily inspection and if a uniform was not suitably presentable, the offender was sent home to change.

To our knowledge, the record for fired keepers by a single curator is over four score. His explanation was that he would fire them until he found a decent one. This curator also fired his wife who was a keeper in the department. At home, she was not allowed to touch his rare books. After she finished reading each page, she had to call him to turn the next page. This marriage began to show signs of stress. The wife had a tame pet rat which she carried with her constantly. As the couple's relationship was deteriorating, he lamented one day that she loved that rat more than she cared about him. He paused pensively for a moment, then said,"But it is truly an exceptional rat!"

Some keepers devised amusing methods for retaliating by harassing curators in subtle ways. One curator demanded that all objects removed from within an enclosure be replaced in exactly the same spot. To ensure that this was done, measurements were taken with a ruler. To destroy the curator's sense of order, keepers moved waterbowls less than one inch daily from the anointed spot with wagers made on how much the dish could be moved before the curator noticed the new placement. In one zoo, the keeper staff was so badly mistreated that they created a "Keeper's Bill of Rights" which was ceremoniously presented to the curator. Included in this document were statements such as all staff must be treated as human beings rather than beasts of burden, and that allowances be made for personal time off the job. The keepers also requested that their personal habits, although bizarre, must not be a topic of discussion in a public forum. The curator's response was predictable and explosive; all keepers were threatened with immediate termination!

It was unusual for keepers to be given time on the job for independent research projects and travel money for professional herpetological conferences or field studies was rare indeed. In fact, should a keeper desire these "curatorial benefits," he was perceived as overly ambitious and a threat to the internal stability of the department. The prevailing philosophy was that a keeper's only responsibility was to clean cages forever and any deviation from this was unacceptable. Needless to say, keepers had virtually no say in the composition of the collection.

Collections were generally structured to reflect the personal interest of the curator but a good part of the pleasure in developing these assemblages seemed to have been the enjoyment derived from showing them off to colleagues. "Are you ready for this?" could be heard in the building as the visitor was hauled from one enclosure to the next. This is not to say that certain curators were not enlightened managers who encouraged their employees in many positive ways. These administrators often directed highly productive departments with meaningful contributions by the entire staff. The message to be taken is that the managerial history of zoo herpetology during this period varied, ranging from a repressive environment directed exclusively by the curator to one that was open and positive for all employees. It is surprising that some of the most dedicated keepers who suffered under unsympathetic curators remained in the profession and it is to their credit that, generally, they did not continue the abusive practices of their former employers as they rose through the administrative labyrinth.

Interactions with Venomous Reptiles in Zoos

Card and Roberts (1996) surveyed incidents of envenomation in zoos between 1970–1995. Yet there were a number of close calls with venomous reptiles which remain unreported. Policies for the handling of these reptiles varied according to the institution; some facilities had explicit procedures for handling potentially dangerous reptiles whereas the policy at other zoos could be characterized as casual indifference. For instance, keepers at one famous zoo would dare each other to lift venomous snakes by sliding their hands beneath the coils. This practice, which involved copperheads, moccasins, and rattlesnakes, continued until the participants were caught by the curator.

In one zoo, a keeper was holding a young black mamba and attempting to remove a dried, stuck shed skin. The snake turned and bit the keeper but the fang fortunately glanced off his thumbnail. Naturally, the keeper released the snake which quickly escaped into the zoo through a gap beneath the door. The snake was discovered shortly thereafter. The same keeper had a difficult time distinguishing venomous coral snakes (*Micrurus*) from false coral snakes (*Erythrolamprus*). His solution was to free-handle both snakes to see if one attempted to bite him; if one of the snakes did so, it was identified as a coral snake. A third episode involving this keeper deserves mention. His task was to clean the habu (*Trimeresurus flavoviridis*) exhibit. To do this, he was required to remove the snake from the exhibit and place it in a garbage can while servicing the cage. To save time, he placed the snake on the rim of the can a few feet behind him, then bent over to begin the cleaning. The habu, poised to strike, focused on the only target within reach—a human derriere. During the course of his duties, it just so happened that the keeper backed up several times and pushed the snake's head back with his rather substantial buttocks, disorienting the snake completely; there was simply too much area to strike!

Feeding venomous reptiles can be hazardous. One keeper used to feed a group of boomslangs (*Dispholidus*) by holding up a tray of dead newborn mice into the exhibit enclosure which stimulated the snakes to launch off of the branches, writhe around in the tray, and feed voraciously. Somehow the keeper's fingers were never viewed as potential food items, even though the snakes crawled over his digits constantly. In another zoo, the curator was convinced that his charges "knew" him personally, accepted him as their caretaker, and would never attempt to bite him as he fed them. Consequently, he fed them with his fingers or used very short forceps for feeding and, in fact, was never bitten during the many thousands of feeding interactions over his career.

Captive king cobras often have difficulty properly shedding

their eyecaps. As a result, a snake with this problem must be taken from its enclosure, held by the attendants, and the eyecaps removed manually. At one midwestern zoo, the curator and two assistants were engaged in this dangerous undertaking but they had not noticed that the snake was ready to shed again. As they held the cobra, it slid out of its old skin like a sausage. The curator, as senior of the department, was entrusted to hold the snake's head. In a flash, the snake partially crawled out of its skin and rose several feet in the air, staring him in the face. Imagine the surprise of the crew as they held an evacuated shed skin with part of an enraged cobra within. Quick thinking saved the day. On the count of three, the handlers threw the snake several feet away, then recaptured it and returned it to the cage. At another zoo, a keeper took the liberty of shedding a golden eyelash viper by hand even though this was expressly forbidden by the curator. When the misdeed was discovered, the keeper was summoned immediately. The curator, in a rage, pointed out that such actions were not permitted in his department under any circumstances; he also said that he had noticed the shedding problem earlier and had planned to remove the skin himself. The keeper answered,"A *good* reptile man would have shed the snake two days earlier!" He was immediately relieved of his position. Several years later, one of us (JBM) was visiting this curator who was still furious about the unmitigated gall of his former keeper—whom he characterized as the most incompetent individual in the profession. The curator raised his arms above his head, looked at his hands with pride and said,"These are the hands that shed the bushmaster and the king cobra!"

One curator was handling a rock rattlesnake on a snake hook when it started to crawl slowly up the shaft toward his hand. He asked the keepers if they had any idea what a rattlesnake's reaction was to human scent. Their response was negative so he allowed the snake to flick its tongue a few times on his finger. Naturally it bit him!

Another zoo herpetologist was despondent since his long standing love affair had collapsed. He concluded that life was no longer worth living so he decided to commit suicide. He believed that a bite from an eastern diamondback rattlesnake, his favorite snake, would be the most heroic way to end his now tattered and insignificant life. He thrust his arm into the zoo exhibit which housed several of these ophidians, shielded his eyes with his other hand, and waited for the inevitable. Nothing happened! After waiting with his arm extended for five minutes in front of their heads, he waved his hand and tapped their snouts. Again, nothing happened. Clearly this was an omen from a higher power; suicide was not meant to be!

Colima, México was a desirable destination for herpetologists for there were several reptile dealers who usually offered interesting reptiles from the region. One zoo herpetologist was proud of his newly acquired BMW sports car and decided to take it to Colima on its maiden voyage. When he visited the local dealers, he saw several gravid Mexican west coast rattlesnakes and cantils which he purchased to bring back to Fort Worth, Texas, where he was employed at the zoo. As he started toward home, his new car coughed a few times and expired. Since he was completely isolated in a remote region and replacement parts were unavailable, he fretted about whether he would be forced to abandon his car there. As luck would have it, a fellow herper from Texas drove by in his pickup truck and noticed the stranded owner and vehicle. He offered to tow the vehicle back to Fort Worth but the only line available was a very short rope. Since necessity is the mother of invention, they attached the vehicles with the flimsy cord; the zoo worker steered the rear car as they set off for home. Since the herper was an avid road collector and speedy driver, every time a snake was seen on the road, he would slam on the brakes and retrieve it. Unfortunately, the zoo worker's reflexes were not keen enough to respond so he slammed into the reinforced bumper of the pickup truck during each sighting. Snakes were plentiful on the road and this catastrophe occurred rather frequently. On top of this, the recently purchased rattlesnakes and cantils gave birth during the return trip and the youngsters escaped into the car where they occupied every suitable hiding place. Although the herpetologist tried to capture them when they were visible, he was mostly unsuccessful for there were many avenues of escape. When he reached Fort Worth, the front of his car was completely demolished and looked like a metal accordion. Every morning, he searched for young snakes in his ravaged car, finding over 50 during a two-week period.

At one zoo, the collection was heavily geared toward venomous snakes, and aquaria housing them were stacked one upon another in the cramped service section until the enclosures nearly reached the ceiling. An adult Egyptian cobra escaped and although the entire area was diligently searched, the snake remained undiscovered, One day, as the curator was cleaning cages, the snake, which had crawled around the cages up to the curator's eye level, struck at his face. According to the curator's analysis, as the snake extended its body in mid-strike, it realized that it was about to strike its *favorite* person. The snake's only option was to close its mouth as it bounced off the curator's cheek. The fact that the cobra did not envenomate convinced the curator that his snakes could identify their favorite human and would never harm him. This curator also crawled into the king cobra's cage periodically when the enclosure needed cleaning. As the snake reared defensively, he tied a handkerchief around its head so the snake could not see him during the cleaning operation. When the curator was finished, he simply untied the cloth and exited the cage.

At the present time, safety is paramount. There are emergency snakebite procedures incorporated as standard policy in zoos, and a computerized list of holdings at each zoo is periodically published (Boyer and Murphy 1994). Recommendations for antivenoms in case of snakebite are available (Minton 1994).

Zoo Herpetologists and the Press

Although zoo directors generally encourage their herpetological employees to be cooperative with reporters, some in herpetology find the prospect of dealing with the press unpleasant. Whenever a snakebite occurs or snakes emerge in the spring, the local press often descends on the herpetological staff for in-depth coverage on the biology of venomous reptiles and the potential for snakebite. This can be an annual ritual in places where snakes are common such as Texas. Most of the time, the zoo herpetologist handles these inquiries with aplomb but there are exceptions. One curator regularly pointed out that people who keep or collect venomous snakes are stupid and deserve to be bitten.

Another curator viewed the press with utter disdain. When a young female reporter scheduled an appointment to interview him at the zoo, he placed trays of thawed, eviscerated mice and beheaded chicks in front of his office door, which forced her to carefully wend her way through the myriad bodies to reach his inner sanctum. Prior to the interview, he worked up a frothy sweat by cleaning crocodilians, thereby ensuring that he would be covered with fish slime and algae when she arrived.

One keeper, on a nationwide television program, assured the

viewers that baby snakes were much more attractive than human babies, as the former resembled the adult whereas the latter looked like a pink, rather disgusting, unformed blob of protoplasm.

Curators and the Zoo Visitor

Considering the curator's view of his kingdom and his ambivalence about the role of the public in his castle, the interaction between the two could be bizarre. Visitors seem predisposed to bang on the glass fronts of snake enclosures. At times, the sound is deafening to humans and is reminiscent of the staccato burst of machine gun fire. Curators have been known to react violently by physically throwing visitors out of their building. Zoo visitors have been subjected to verbal abuse as well. One curator, upon noticing a visitor flicking her tongue at a snake in a exhibit, loudly yelled that she should remove her tongue from the glass and put it back in her mouth where it belonged. Not all visitors accepted the curator's rebuke passively and shouting matches could be heard throughout the building.

While knowing that visitors were essential to continued paychecks, curators were often indifferent about the public's presence in the zoo. Some desperately worked to avoid any interaction with the public, including public speaking. Nowadays, as resources shrink and zoo conservation programs require public support, curators must be visible and effective advocates of their institution's mission. The loss of biodiversity and threats to amphibian and reptile conservation must be effectively presented to a wide audience; the modern zoo herpetologist is uniquely suited to this task.

Practical Jokes

The director of a small southwestern zoo built a planted outdoor aviary with funds donated by a well-known zoo supporter. The donor requested that the new exhibit be named in honor of his family and that an elaborate dedication ceremony be arranged with local dignitaries in attendance. Funds were available for construction but there were no additional monies to buy expensive birds so the director stocked the aviary with parakeets solicited from the community. On the dedication day, as the distinguished guests arrived, the director realized that the aviary seemed unusually quiet—no chattering, multi-hued parakeets were flitting through the branches. As the group peered into the aviary, the only creatures in view were some extremely well-fed Texas ratsnakes draped over the branches. One of the director's colleagues had slipped in the night before and released the snakes into the exhibit.

A zoo keeper had a large, tame Gulf Coast toad which lived for years at the zoo. Every morning, he retrieved the anuran from its aquarium and placed it on his working cart as he serviced his exhibits. The toad did not attempt to escape but quietly sat on the cart. Throughout the day, the keeper would feed mealworms to his pet. Another keeper, on his way to work, found a dead toad on the road which resembled the pet toad. As the first keeper was busy at work, the second keeper picked the pet toad off the cart, deftly substituted the dead toad, yelled that he had been bitten by it, then threw the dead toad on the floor and squashed it with his foot. The first keeper, unaware of the switch, grabbed his coworker and tried to beat him into submission. Revenge was sweet. The aggrieved keeper later slipped a snapping turtle into the perpetrator's aquarium of exotic tropical fishes.

One zoo herpetologist was asked to appear on a local television program to talk about venomous snakes. To spice up his presentation, he placed a live rattlesnake, moccasin, and copperhead in a cloth sack and started for the studio. He was bitten by one of the snakes on his leg through the bag but he could not identify the culprit. Fortunately, crotalid polyvalent antivenom was the drug of choice so the issue was somewhat moot. Convalescence was painful and arduous; he slowly hobbled around on crutches for many weeks. One day, his colleague removed the bolts which held the crutches together. As the victim unsteadily stood and placed his weight on them, the crutches collapsed; he fell down the stairs, amusing his companion greatly. Recovery was extended by a few weeks.

One keeper was fond of Exuma Island rock iguanas and he had a tame specimen at home. During the summer, the lizard was kept in an outdoor enclosure from which it escaped. A thorough search of the neighborhood was mounted but the lizard was nowhere to be found. The keeper was crestfallen. A coworker found a deceased specimen of similar size in the freezer at the zoo. Since both keepers drove to work together each morning, the joker put the thawed carcass on the road, yelled that he saw the escaped saurian and promptly drove over it so that it wouldn't escape again. The exasperated lizard owner was not at all pleased!

The director at a major zoo was inspecting the reptile house with the staff. As he leaned over the railing to examine an exhibit closely, he failed to notice some foreign material on the rail. Earlier, a zoo visitor had placed his child on top of the railing whereupon the youngster promptly defecated. When the director checked his shirt, there was a prominent horizontal stripe emblazoned on the garment. He called each member of the staff in turn over to the exhibit and demanded that each bend over the railing to view the exhibit closely for signs of uncleanliness. As a result, each had a similar design on his shirt. Although the zoo had a standard uniform policy, matching brown stripes had not been envisioned.

In 1953, Roger Conant described a new subspecies of the diamondback watersnake, the Tabasco watersnake (*Nerodia rhombifer werleri*) from México, in honor of his colleague, John Werler, the now-retired Director of the Houston Zoo. The more common nominate form was the snake of choice to feed several king cobras at the zoo, so periodic shipments of the watersnakes arrived at the zoo from an animal dealer. A new keeper was told to feed several of the food snakes to the cobras. After the cobras had dined, the keeper was told that the snakes which he had used were, in fact, the very rare namesake of the Director and this serious transgression was grounds for immediate termination. Werler continued the ruse and berated the keeper forcefully for his oversight and carelessness. Eventually, the keeper was told of the joke but some anxious moments preceded the confession.

The Future of Zoo Herpetology

At the annual meeting of the International Herpetological Symposium in San Antonio, Texas in 1996, Curator David Grow from the Oklahoma City Zoo gave a disturbing presentation. His message was simple and direct. There is a trend in zoos of the United States to reduce space and financial support for herpetological programs. In spite of the fact that reptiles and amphibians rank high in visitor popularity (Marcellini and Jenssen 1988), those administrators entrusted with the responsibility of allocating resources have been trapped in a phylogenetic and financial mindset: mammals rank first, followed by birds, fishes and large aquaria, and finally herps. Grow pointed out that there has only been one herpetarium constructed in the United States during the last decade. Moreover, when a new exhibit is planned, precious little space is devoted to herps.

We would like to take Grow's argument a step beyond. If one reviews the index of Card and Murphy (in press), there are roughly 175 names listed of people who have worked in herpetological facilities, mostly reptile buildings. In these herpetologically saturated environments, training, techniques, and novel ideas for captive management have been developed and honed in an impressive way. The beneficiaries have been the animals housed at the zoo. Lately, there has been a trend in zoo planning to stress biodiversity and total immersion mixed exhibits with a wide variety of animals and plants. Although we applaud these efforts, there are several deleterious side effects. The first problem is keepers are trained to be generalists rather than specialists. The second is that the mechanical and electrical support equipment needed to ensure sophisticated environmental parameters for herps is rarely included in a facility designed mostly for mammals and birds. The third is that the smaller or less dramatic amphibians and reptiles tend to pale in comparison with the more active endotherms and may be overlooked. The last is the opportunity for teaching herpetology in a zoo setting will be diluted in a large, generalized exhibit. Successful exhibits and programs can and have been developed for herpetological facilities that address the biology of amphibians and reptiles in an interesting way (see Chiszar et al. 1993; Marcellini and Murphy 1998; Murphy and Chiszar 1989, for examples).

Zoo herpetology has a vivid and rich history, but appears to be declining. Unless there is a reversal of attitude by the majority of zoo professionals, the zoo visitor may have to be content with the occasional large python, Komodo monitor, giant tortoise, massive crocodilian, or other equally dramatic and hardy examples. The danger is that many of the less glamorous species will be ignored and the opportunities for education will be lost. That is truly a shame.

Acknowledgments.—We are grateful to Judith A. Block for reading the manuscript and offering many helpful suggestions. Jonathan Campbell, David Chiszar, and Christen Wemmer discussed their impressions of zoo workers with us. Kraig Adler, Joseph T. Collins, Jaren Horsley, Dale Marcellini, and the staff of the herpetology department at the National Zoo, Charles Coutris, Michael Davenport, Béla Demeter, Monika Holland, Roger Rosscoe, and Trooper Walsh read an early draft of the paper. John Arnett, William Austin, John Banks, Peter Brazaitis, Patrick Burchfield, J. S. Dobbs, James Langhammer, Tommy Logan, John Werler, William Xanten, and Robert Zappalorti shared their experiences with us.

TECHNIQUES

A Portable Device for Restraining Frogs

MICHELLE T. CHRISTY
School of Biological Sciences, The University of Sydney
New South Wales 2006, Australia

Researchers often conduct field studies in relatively isolated areas without assistance. In many instances access by foot only is possible, which encourages the use of lightweight, durable, waterproof, and easily transportable equipment. It is sometimes necessary for captured animals to be restrained, such as during the application of tags or the fitting of radio-tracking devices (e.g., Carpenter 1954; Kluge 1981; Martof 1953; Prestt 1971). Restricting the movement of study animals is often difficult if the researcher is working alone.

Many devices for restraining animals have been described (e.g., Fowler 1978; Jones and Hayes-Odum 1994; Quinn and Jones 1974), but few examples exist for amphibians. Heyer et al. (1994) suggest that salamanders and frogs should be placed in a wet zip-lock bag and tagged directly through the plastic. Although the technique works for some tagging methods, it is not always suitable, particularly when fitting radio-tracking devices where the researcher must have access around the body. Here I describe an alternative method for restraining frogs while fitting tracking devices or applying tags. The device is light, durable and waterproof, quickly and safely restrains frogs, and can be used by a single worker.

The device, known as the "strapper," consists of a base of about 20 cm x 20 cm x 1 cm, to which are attached four elasticised straps (Fig. 1). It weighs approximately 180–250 g depending on the material and size of the base (i.e., a cedar base weighs approximately 180 g, polypropylene base weighs approximately 225 g). The base is likely to become wet, so should be made of moisture resistant wood or polypropylene. Each of the four elastic straps are secured to the base with a 10 mm stainless steel countersunk screw and threaded through a shoulder strap slide (as used in brassieres) and a strip of loop and hook fastening tape (e.g., Velcro™) is sewn to the topside of the unsecured end. The four straps are gapped by 1 cm, 2.5 cm, and 1 cm in sequence, respectively. Four strips of the complementary surface of fastening tape are attached to the underside of the base with matching spacing.

Wrapping damp gauze around the straightened legs and tightening two of the elastic straps around the waist and thighs secures the frog, holding the legs firmly together. The upper body is positioned inside the loop of one of the remaining two elastic straps with the arms pinned in front of the tightened strap. Again, damp gauze should be used to provide moisture, cover the frog's eyes and protect the frog from potential skin damage. Once tightened, the straps are doubled back and secured to the underside of the board using the Velcro. This position inhibits the frog's movements and thus decreases the risk of injury during handling.

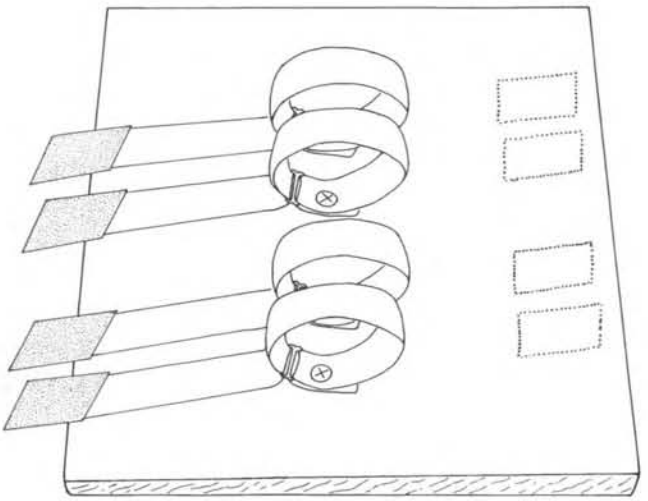

FIG. 1. The strapper incorporates four lengths of elastic secured to the base. The elastic is threaded through a shoulder slide and secured using Velcro™.

The two head straps can accommodate size variation in restraining frogs (i.e., the inside strap fits smaller frogs, the outside strap larger ones). These dimensions allow securing of frogs with a small (2.5 cm) to relatively large (15 cm) snout-urostyle length. However, by increasing or decreasing the gaps between the straps, the strapper can be modified to accommodate most size ranges.

During the past 24 months, the strapper has been used to secure in excess of 600 green and golden bell frogs (*Litoria aurea*) during Passive Integrated Transponder (PIT) implantation procedures or attachment of transmitters on waist belts. It would be possible to use only the lower body straps, or upper body straps, or further modify the strapper to make it compatible with alternative transmitter attachment or tagging methods (e.g., Emlen 1968; Kaplan 1958; Kluge 1981; Rathbun and Murphy 1996). The use of the strapper adds approximately 30 seconds to the PIT tagging procedure, but needs only to be used when the researcher's dexterity is compromised or the frog is uncontrollable. The fitting of the waist belt transmitter, from capture to release, takes approximately five minutes using the strapper. Thus far no adverse effects of using this method have been noted. After 24 months of field use, the strapper shows no sign of deterioration, however, I expect the elastic straps will need to be replaced bi-yearly, depending on use.

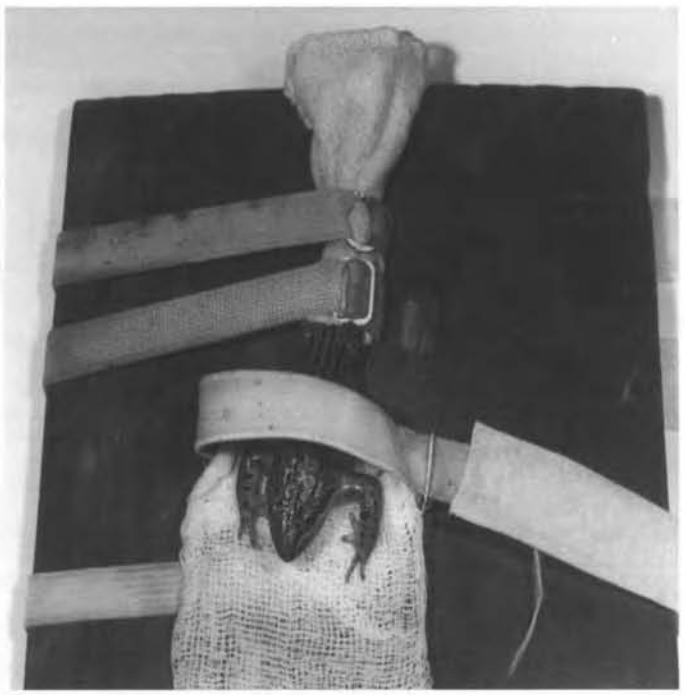

FIG. 2. The frog is secured by tightening two of the elastic straps around the waist and thighs and one of the remaining straps around the upper body. Damp gauze provides moisture and protection from potential skin damage.

In my work, the reasons for using such a device are four-fold. First, unlike some frog species, *L. aurea* can be feisty and difficult to handle. Second, as they are recognized in New South Wales as 'endangered' on Schedule 1 of the Threatened Species Conservation Act 1995, extreme care must be taken to minimize potential stress and damage to individuals. Those in the smaller size range (e.g., 35–40 mm) are most susceptible. Third, some applications, such as the fitting of transmitter belts, can be more quickly and easily completed if the frog is restrained using the strapper, leaving the researcher's hands free. It is particularly useful when working alone. Fourth, the strapper is particularly useful for researchers inexperienced or lacking confidence in PIT tagging or handling frogs in general. In most cases, the strapper has decreased handling time required to restrain difficult individuals, thus reducing the time taken to perform the tasks and, ultimately, the stress experienced by the animal.

Acknowledgments.—The work for which the strapper was developed is funded by a scholarship provided by the Olympic Coordination Authority. A. Greer, C. Dickman, and R. Sadlier provided useful comments on earlier drafts of this manuscript.

Several reliable methods to mark anurans at the postlarval stage have been published (Elmberg 1989; Emlen 1968; Ferner 1979; Howard 1978; Nace 1982; Rice 1993; Robertson 1984; Ryan 1980; Wells 1977, 1978). However, few practical techniques to mark anuran larvae exist. This is undoubtedly due to the delicate tissues and lack of limbs or digits at this life stage. Commonly used methods include clipping notches on the tail fin (Turner 1960), staining with neutral red (Guttman and Creasey 1973; Herreid and Kinney 1966; Travis 1981), and injecting or spraying with dyes (Seale and Boraas 1974; Taylor and Deegan 1982). However, these methods have various limitations. The effects of fin clipping on growth, swimming behavior, and mortality of larvae have not been evaluated. Although neutral red staining is easy to perform, it has short-term permanence (Guttman and Creasey 1973), causes decreased growth (Travis 1981), and can not be used for individual identification. Taylor and Deegan's technique (1982) of spraying pigments on several larvae at once is useful because individuals do not need to be handled. However, the authors reported that their methods cause some mortality and require expensive equipment. Injecting pigments mixed with an organic solvent directly into larval tissues causes no mortality, but some preliminary work is necessary to develop the proper solvent formulation (Seale and Boraas 1974). Here we report on a useful alternative to the above methods for individually marking large numbers of larval anurans. In addition to evaluating the effects of our marker on survivorship and growth, we also quantified its effects on the locomotor behavior of the larvae.

Bullfrog larvae (*Rana catesbeiana*) were collected at Miami University's Ecology Research Center, Butler County, Ohio, USA, during November 1995. These larvae were held in a 500 L aquarium designed to provide a continuous flow of dechlorinated water at 18°C. Larvae were held under a 12L:12D photoperiod and fed trout chow *ad libitum*. On 19 May 1996 we selected 20 larvae at the premetamorphic stage (stage 25, Gosner 1960) to use in the evaluation of our tagging method. Larvae were weighed on a Mettler balance (to nearest 0.01g) and measured with Vernier calipers (SVL to nearest 1.00 mm), and randomly placed into either the tagged or untagged group (N = 10 per treatment). Each treatment group was maintained in a 37 L aquarium with a continuous flow of dechlorinated water at 25°C.

Larvae outfitted with tags were anesthetized via submersion in a solution of tricaine methanesulfonate (approximately 0.050 g per L dechlorinated water) until movement ceased. Individual larvae were then removed from anesthesia and a single stitch of polyester thread (thread diam. = 0.20 mm, needle diam. = 0.75 mm) was made through the base of the tail, directly into the musculature and slightly above the midline. Attached to the thread was a label made of plastic field flagging (5 mm x 5 mm) upon which a unique number was written in waterproof ink. The two ends of the thread were tied with enough slack to allow the label to remain free of the fin and allow for growth of the tail (Fig. 1). Total time required to tag all individuals was kept to a minimum by ensuring that two larvae were under anesthesia concurrently, such that each time a larva was removed for tag application another was added to the tricaine methanesulfonate.

Mass and SVL of all tagged and untagged larvae were measured at the beginning and every 2 wk until the first individual achieved forelimb emergence (stage 42, Gosner 1960), after wk 8. Comparisons of these measurements between tagged and untagged larvae were made with Student's t-tests within each 2 wk interval. Repeated-measures analyses among all time periods were not possible since the identity of individual untagged larvae was unknown between consecutive weeks. Upon reaching stage 42, final mass and SVL measurements were made on individual larvae, and the time spent in the experiment was also noted as an indication of metamorphic duration. Mass and SVL at stage 42, as well as time spent in the experiment, were compared between tagged and untagged larvae with Student's t-tests.

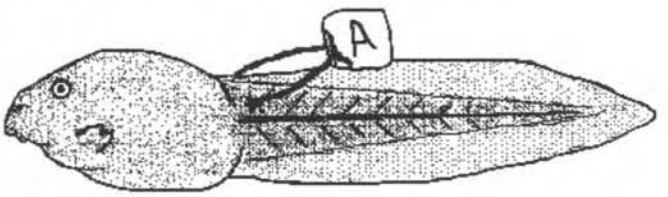

FIG. 1. Diagrammatic representation of tag location on a larval *Rana catesbeiana*. Tags are made of polyester thread and field flagging, and attached to the larva with a single stitch applied at the proximal end of the tail slightly above midline.

Locomotor tests were conducted at wk 6, at which time larvae had small to moderate hindlimbs (stages 34–38), between 1200 and 1700 h. The locomotor behavior of larvae was evaluated by placing individual larvae into 1 L crystallizing dishes containing approximately 600 ml of dechlorinated water at 25 C. Following a 5 min acclimation period, locomotor behavior of the animals was monitored using a video based data acquisition system, the Videomex-V (Columbus Instruments, Columbus, OH). This system measured the distance traveled (cm) and average velocity (cm/sec) for 30 sec intervals during the total 5 min period. The two aspects of locomotor behavior we examined were the total distance traveled and the maximum velocity of each larva. Total distance traveled was calculated by summing the distance traveled over all of the 30 sec intervals. Maximum average velocity was the fastest velocity measurement recorded in one of the sampling intervals. Comparisons between tagged and untagged larvae were conducted using separate Student's t-tests.

Application of a tag required approximately 5–10 min per individual, but most of this time was spent waiting for the anesthesia to take effect; the actual stitching and tying of the tag could be performed in < 1 min. Little blood loss was observed, but after several days the application site on most larvae became slightly inflamed, however, no infections were observed. One label fell off the day after the initiation of the experiment; however, the thread was still attached to the tail of this individual. Upon reapplication, this tag and all the others remained attached during the course of the experiment. The only mortality observed during the experiment was an untagged individual that died between wk 6 and wk 8.

There was no significant difference in mean mass between tagged and untagged larvae from 0–10 wk after the start of the experiment ($t \leq 1.11$, df = 17–18, $P \geq 0.281$ for all time intervals; Fig. 2A). Both groups increased in mass between wk 0 and wk 10. There was also no significant difference in SVL between tagged and untagged larvae during this time period ($t \leq 1.09$, df = 17–18 $P \geq 0.288$ for all time intervals; Fig. 2B). The two groups increased only slightly in snout-vent length through the 10 weeks, indicating that they were near maximum length at the initiation of the study. Since the tags did not affect growth rates, it was not unexpected that there were also no significant differences among final mean mass, mean SVL, nor mean time spent in the experiment, between tagged and untagged larvae at stage 42 ($t \leq 0.906$, df = 17, $P \geq 0.377$ for all parameters). Tagging the larvae also did not affect the locomotor activities we measured, since there were no significant differences in total distance traveled ($t = 1.591$, df = 18, $P = 0.129$) or maximum average velocity ($t = 0.094$, df = 18, $P = 0.926$) between tagged and untagged larvae.

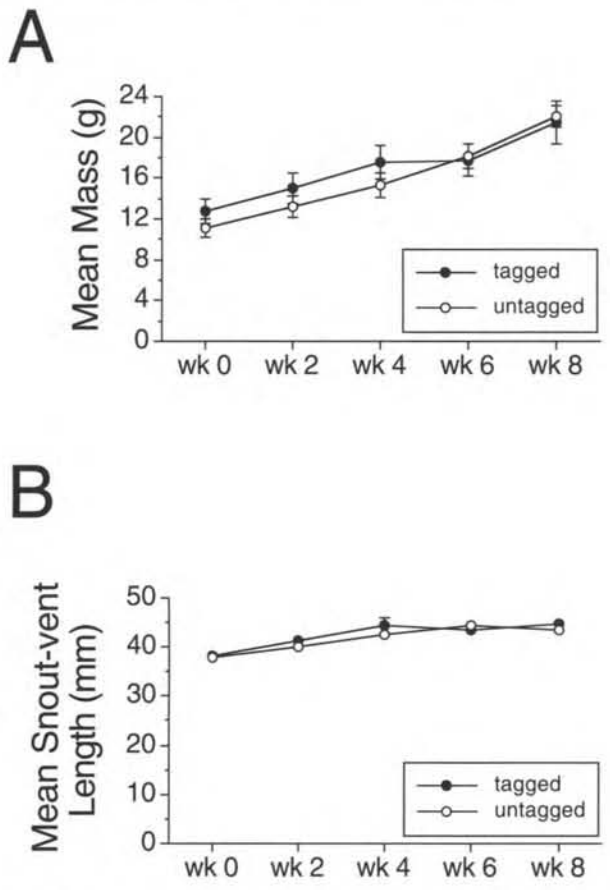

FIG. 2. Mean mass (A) and mean SVL (B) of tagged and untagged *Rana catesbeiana* larvae at 2-wk intervals. Bars indicate ± 1 SE. Sample sizes were 10 in each group, except on week 8, when there were only 9 untagged larvae due to mortality. Larvae were initially at Gosner stage 25 and began to metamorphose after wk 8. There were no significant differences between groups for either parameter at any week.

Our tagging method provides an alternative to other methods because the materials are inexpensive, can be purchased at local stores, and can be applied by one person with a minimum of training. Since individuals can be given a unique number as well as a color-code, many more larvae can be marked and recognition of each is easy. Furthermore, the empirical evidence presented above indicates that the tags are long-lasting and cause no adverse effects on growth, survivorship, or normal activity. We have marked over 250 *R. catesbeiana* larvae thus far (60 in one day) with both individual and color-coded labels. Individuals as small as 1.00 g and 18 mm SVL have been tagged, and smaller individuals could probably be marked by using thinner needles and thread. Tags have remained attached on at least 60% of our larvae that survived from early premetamorphic stages to metamorphosis (8–14 mo in the laboratory). The important step in the procedure is to ensure that the thread is knotted tightly, since most tag loss results from improperly applied tags rather than from the tag being torn from the larva's body.

This tagging method would be especially useful for laboratory evaluations of behavior because such experiments often require identification of individuals without handling. Our techniques could also be used for certain field studies in the absence of predators and snagging objects. However, the potential utilization of our tags for studies examining exercise physiology or forced locomotion might be limited, as the effects of the tags on hydrodynamic properties and muscle performance of anuran larvae need to be evaluated prior to experimentation.

Acknowledgments.—We thank J. Litzgus for reviewing earlier drafts of the manuscript, and M. Szeremet for taking care of the larvae. All experiments were conducted with the knowledge and approval of Miami University's Institutional Animal Care Committee (protocol #96-334).

Sticky Traps: An Effective Way to Capture Small Terrestrial Lizards

SHARON DOWNES

New South Wales 2006, Australia
e-mail (SD): sdownes@bio.usyd.edu.au

In their endeavors to capture small, fast, terrestrial lizards, herpetologists have devised an impressive variety of sampling techniques. Among those most widely used are pitfall trapping, rubber bands, hand collection, and noosing; more recently, refuge tubes, baited lizard sticks, and glue sticks and traps have been used (for a review see Durtsche 1996; Whiting 1998). Although many of these techniques are efficient, they are either labor intensive (e.g., pitfall trapping), demand that the collector has a certain degree of prior experience (e.g., rubber bands, hand collection, baited lizard sticks, glue sticks), require more than one person to be effective (e.g., refuge tubes), or are not well suited to capturing small animals (e.g., noosing, glue traps). In addition, many of these techniques are not suitable in urban environments which often consist of concrete structures surrounded by long dense grasses. Here we report a method used to catch large numbers of small, fast, terrestrial lizards (common garden skinks, *Lampropholis guichenoti*, *L. delicata*, *Saproscincus mustelinus*: ≤ 45 mm snout-vent length; ≤ 1.5 g) around urban environments in southeastern Australia. Our method is inexpensive, simple, and extremely effective. The procedure can be performed by one person, demands no previous lizard catching experience, and is ideally suited to urban landscapes.

Our technique consists of placing 50 mm wide, clear packing tape (e.g., many commercial brands are readily available in newsagencies), adhesive-side uppermost, on hard flat surfaces enroute to basking sites. To reduce the stickiness of the tape and facilitate removal without damage to the animal, it is adhered once to a cotton fabric, and then removed and immediately used. The tapes vary in length depending on the geometry of the surface (but rarely exceed 600 mm), and are fastened by placing smaller pieces of transparent tape adhesive-side down on each end and in contact with the surface. During strong winds, rocks are also positioned on both ends of the tape, and occasionally (especially for long tapes) in the center. The tapes are strategically placed (see below), but they are always away from obvious ant trails. Unless the traps are visited at regular intervals (at least 3–5 min), it is imperative that they are placed in the shade to prevent thermal stress to captured lizards.

Skinks walk onto the tape and the soles of their feet fasten to the adhesive surface. The ventral surface and tail of the skink often adhere also; and occasionally, the neck of the skink becomes stuck. Although held fast by the tape, we never have any difficulty removing skinks from the traps. The skink is very slowly removed by degrees from the tape, beginning at the head and working toward the tail which is usually in a curved configuration. Once the body of the skink is free, the tail is gently lifted from the tape by moving the unstuck body of the lizard toward the tip of the tail and following the curvature. The speed at which the skink is removed is positively correlated with the size of the captured individual and negatively correlated with the stickiness of the trap. The lizard is removed without ill effect, and without the aid of solvents or lubricants. As this can be done in situ, traps can be left in place and used repeatedly for a full day.

We employed our technique from November 1996 through March 1997, at a number of urban cemeteries and parks around Sydney, Australia, where garden skinks are locally abundant (10 lizards/2m^2; S. Downes, unpubl. data). We scanned small areas (20 x 50 m) of habitat for garden skinks and set several traps (8–10 at a time) on suitable sites. One of us continually checked the traps (moving from one trap to the next in the order in which they were placed) and removed captured skinks. During early afternoon (the most active period of the day for our skinks during summer), up to 30 garden skinks (both adults and hatchlings) would be collected each hour using our method, compared with around 12 skinks per hour using hand collection. Undergraduate students with little or no prior experience in animal handling or capture enjoyed similar success using our traps. No skinks were killed, although a small proportion (around 3–5%) lost the tip of their tail through struggling to escape.

We suspect that our method is particularly successful for capturing large numbers of small lizards that display aggregative social behaviors: garden skinks are highly social (Torr 1990) and after one animal becomes stuck to a trap, others typically investigate and also become entrapped (see also Whiting 1998). Although we used our method primarily to capture small lizards, we have employed a similar technique (using a commercial cockroach trap) to successfully catch larger terrestrial lizards from rock crevices along urban creeks (e.g., water skinks, *Eulamprus quoyii*, to 10 cm SVL and 40 g: see also Bauer and Sadlier 1992). In this case, our technique involves attracting a lizard to the trap either by adhering a live cricket to the center of the strip, or luring it using a cricket tied to a fishing line (note however, that the animals were held for only a short time using this method). We envisage that employing similar baiting tactics with live insects would further improve the rate that lizards are captured on the sticky traps (see also Whiting 1998). Additionally, when used intermittently with conventional methods, sticky traps may be well suited to catching individuals in mark-recapture studies that develop aversion to the standard capture technique.

Our traps take only minutes to set up and may be especially useful in areas where dense vegetation predominates among a few basking rocks, or rocky substrate hinders excavation for pit traps. They may also prove effective when used in place of conventional pit traps in conjunction with drift fencing (see also Bauer and Sadlier 1992). This non-destructive technique should enable researchers (even those with limited prior experience in capturing lizards) to successfully obtain very large numbers of small locally abundant species of lizards, including hatchlings and juveniles that are otherwise hard to detect.

Acknowledgments.—We thank P. Doughty, H. Gyragossian, P. Harlow, R. Shine, and P. Whitaker for their advice and valuable comments on the manuscript. We used this method to collect data for projects that were approved by the University of Sydney Animal Care and Ethics Committee; conducted under Research Permit B1646 issued by the NSW National Parks and Wildlife Service; and funded by an Australian Postgraduate Award, AFUW River Group Grant, SSAR Grant-in-Herpetology, Royal Zoological Society of NSW Ethel Mary Reed Grant, Ecological Society of Australia Student Travel Award (to SD), and Fundación Gran Mariscal de Ayacucho Scholarship (to PB).

Comparison of Histological Staining Procedures for Skeletochronological Studies

C. REED ROSSELL, JR.
and
JOSIAH L. SHEEHAN
Department of Environmental Studies, Warren Wilson College
Asheville, North Carolina 28815, USA

e-mail (CRR): rrossell@warren-wilson.edu

Skeletochronology is the study of growth periodicity in the mineralized bone structure of animals (Castanet et al. 1993). This technique can be used to accurately estimate the age of amphibians whose annual growth patterns are cyclical (Castanet et al. 1993). Because of its reliability, skeletochronology has become widely used by ecologists studying salamander populations (Wake and Castanet 1995).

Preparing samples for skeletochronological analysis is a fairly complex process (Castanet and Smirina 1990). One important component is the selection and proper use of stains (Castanet et al. 1993). Hematoxylin and eosin (H&E) are the standard stains used in histological studies (Davenport 1960; Humason 1972). However, the protocol for using these stains is tedious and time consuming.

We examined an alternative staining procedure to simplify and reduce sample processing time. We compared the Jordet J-322 Dip-Quick Stains (Jorgensen Laboratories, Loveland, Colorado, USA) to the standard H&E stains for estimating the age of individual salamanders.

From October 1995 through April 1996 the longest phalange from the hind foot of 63 *Ambystoma talpoideum* were collected using a surgical scalpel. Samples were fixed in 10% buffered neutral formalin, then stored in 70% ethanol (Wake and Castanet 1995). Phalanges were decalcified in 3% nitric acid and washed in tap water (Humason 1972), and standard histologic procedures were used for preparing samples (Davenport 1960; Humason 1972). Phalanges were cross-sectioned at 5 µm and processed at the Animal Disease Diagnostic Laboratory in Asheville, North Carolina.

Each sample (N = 63) was replicated for comparing the two staining procedures. The H&E procedure consisted of immersing each sample in each of the following: xylene (15 min), 100% ethanol (2 min), 95% ethanol (2 min), 70% ethanol (2 min), distilled water (2 min), Mayer's Hematoxylin (15 min), tap water (10 min), 80% ethanol (2 min), eosin (3 min), 95% ethanol (3 min), 100% ethanol (3 min), and xylene (3 min). The Dip-Quick procedure entailed dipping each sample into fixative (methyl alcohol) five times, stain #2 (eosin, sodium azide, and buffer solution) eight times, counter stain #3 (thiazine, sodium azide, and buffer solution) three times, and rinsing with distilled water five times. The duration of each dip was ca. one second.

After staining, cover slips were placed over all samples with the toluene solution Permount (Fisher Scientific, Fair Lawn, New Jersey, USA). One of the authors and a lab assistant counted growth marks, following methods described by Castanet et al. (1993). Only a few discrepancies occurred between counts. These slides were re-evaluated and discussed until a consensus was reached.

The Dip-Quick stains effectively highlighted growth marks in all samples. The number produced by the Dip-Quick stains was identical to those produced by the H&E stains in 92% of the samples. The Dip-Quick stains produced an additional growth mark in one sample, and the H&E stains produced an additional growth mark in four samples. The clarity of the growth marks produced by the Dip-Quick stains was comparable, if not better, than that produced by the H&E stains.

Compared to the H&E procedure, the Dip-Quick procedure saved a considerable amount of processing time and was much simpler to use. The Dip-Quick stains required ca. 21 sec/slide, and 2–3 slides could be processed simultaneously (12 min/100 slides). In contrast, the H&E procedure required ca. 62 min/slide, and 30 slides could be processed simultaneously (206 min/100 slides). Thus, the Dip-Quick method resulted in a time savings of ca. 3 h/100 slides.

The Dip-Quick stains were more expensive than the H&E stains (US $40/100 ml for the Dip-Quick refill kit vs. $17.90/500 ml Mayer's Hematoxylin and $35.80/500 ml eosin) [Fisher Catalogue 1996]. However, comparing the actual costs was difficult because the H&E stains are reusable if filtered regularly (D. Seal, pers. comm., Animal Disease Diagnostic Laboratory, Asheville, North Carolina).

Skeletochronology is currently one of the most accurate and sophisticated techniques available for aging salamanders (Castanet and Smirina 1990; Castanet et al. 1993). The Jordet J-322 Dip-Quick Stains proved to be an effective alternative for staining *A. talpoideum* samples for skeletochronological analysis. The procedure is straightforward and saves a considerable amount of processing time. Although more expensive than the standard stains, the Dip-Quick stains are not cost prohibitive. Therefore, we recommend the Dip-Quick stains as an alternative for staining samples for skeletochronological studies of salamanders. However, the Dip-Quick stains may not be appropriate for large-scale clinic or diagnostic use (i.e, processing >100 slides/day). The Dip-Quick stains need to be refilled periodically as they evaporate, or replaced when they begin showing signs of discoloration.

Acknowledgments.—We thank the North Carolina Academy of Science Yarbrough Grant Committee for funding this research, William Rapp and Deloress Seal at the Animal Disease Diagnostic Lab for lab assistance, and Yanu Gallimore for counting growth marks. Laurence Hardy, William Rapp, Larry Raymond, Irene Rossell, and one anonymous reviewer provided valuable comments on earlier drafts of this manuscript.

FIG. 2. Undersurface of device showing the framework upon which the boards are mounted, and the plastic water bottle in place.

The positioning of the device is vital to maximize access to trapped animals. The direction of pool water flow towards the skimmer box means that a weakened animal will float towards, and often into, the skimmer box where ultimately it will drown. The device was therefore placed over the skimmer box as shown in Fig. 2. Its first observed success, one week after its installation, was the emergence via the inclined ramp of a juvenile viper, *Vipera berus*.

Mites are common ectoparasites that can cause serious health problems for squamate reptiles—particularly under captive conditions (Frye 1981; Lane and Mader 1996; Mader 1989; Marcus 1983). Mites can be difficult to extirpate completely (e.g., Mader 1989; Montanucci 1997), and as a result, numerous commercial products are now available to kill these pests (e.g., Abrahams 1992; Boyer and Boyer 1991). However, some of these products are unsatisfactory for one or more reasons, including toxicity, the need for veterinary direction, required changes in husbandry, high cost, or a lack of long-term efficacy (Mahaney 1995; Montanucci 1997).

Several non-commercial techniques have been described for eradicating mites from captive reptiles and their surroundings. One method traps mites by simply lining the perimeter of the animal's enclosure with masking tape (Mahaney 1995). Yet despite its ease of application, this method only removes dispersing individuals, and thus mites that remain in the substratum, on refugia in the enclosure, or on the animals themselves, will not be captured.

Recently, Montanucci (1997) described a procedure for eradicating mites by selectively removing the most critical stages of their life cycle—gravid females and egg cases. Although this method is reportedly effective, the process seems inordinately elaborate, and may require a substantial time investment. Specifically, this procedure includes a twice-weekly washing of the cage and refugia, and manual removal of gravid female mites and egg cases. Due to the lengthy life cycle of these pests, this process may ultimately take more than a month to eliminate an entire mite population (Montanucci 1997).

In our lab, we kill mites living on reptiles by immersing the reptiles in vegetable oil. The oil entraps and subsequently suffocates the mites by occluding their respiratory passages. This method offers the advantages of low cost and safety while completely eradicating the entire mite population with a single application. After several years of refinement, we have improved the efficacy of this method which is described below.

Unlike some methods (e.g., Mahaney 1995; Montanucci 1997), ours works by killing the mites that are on the animals. If one starts with a mite-free environment (see below), prevention of reinfestation is reduced to a process of killing mites on all new reptiles before they are introduced into established vivaria.

To eliminate mites from terraria, we have used a variety of mite-killing solutions including 70% isopropanol (rubbing alcohol), 10% bleach or ammonia, or dish or laundry detergent and hot water. The terrarium, and all non-living items that have come in contact with mites, are scrubbed and soaked for 5–10 min with one of these solutions, rinsed thoroughly, and air dried until no odors are detectable. Mites can also be removed or killed by spraying these items with the pressure from a garden hose (Montanucci 1997), but care should be taken to ensure that the treatment is thorough, because if critical areas are neglected (e.g., plastic frames of some aquaria, porous rocks, etc.), a reinfestation is likely to occur. For this reason, we generally dispose of the substratum (e.g., soil, sand, gravel, etc.) rather than attempting to disinfect and dry it.

To kill mites on reptiles, we thoroughly coat each animal with vegetable oil. In our experience, neither the type nor the brand of vegetable oil appears to affect the outcome. First, the animal is cooled to room temperature (ca. 20°C) to facilitate handling, then it is placed in a large container (e.g., a size-matched bowl, tub, or bucket) with enough oil to partially submerge the animal (i.e., one-third to one-half of the animal's height). We then use our hands to drip the oil liberally over the animal taking care to completely cover and massage the oil over all parts of the body (e.g., neck and body skin folds, joints of appendages, cloacal region, all parts of the head including the region surrounding the eyes). We have not witnessed any signs of distress from dripping the oil around the eyes, nares, or mouth. Highly infested animals, or those with large imbricate scales (e.g., desert spiny lizards, *Sceloporus magister*), are massaged in the oil for up to 1 min to ensure that the animal is thoroughly coated. The animals are then blotted with paper towels and held in a clean cage with a newspaper lining until the oily sheen on their scales diminishes (1–3 days). Water, heat sources, and refugia are provided, although we typically do not feed the animals during this time.

Reptiles that we have subjected to this treatment apparently are

unharmed; however, the oil-immersion procedure often elicits ecdysis soon after treatment. In one instance, four of six juvenile boa constrictors (*Boa constrictor*) exhibited dysecdysis following the oil treatment. The remaining unshed patches of old skin were easily removed after the snakes had been soaked in warm water for 15 min (see Rossi 1996).

Over the past seven years, this method has been successfully used on 17 species of lizards representing 10 genera and five families. We have also used the method on desert tortoises (*Gopherus agassizii*) and boa constrictors (*Boa constrictor*)—the latter infected with the snake mite *Ophionyssus natricis*. We have not observed a reinfestation following this procedure.

Given the simplicity and efficiency of the oil-immersion technique, we both use and recommend the procedure as a preventative measure when new reptiles are introduced into established mite-free collections. Recently, we "de-mited" approximately 60 field-caught chuckwallas (*Sauromalus obesus*) that were infested with mites (probably *Hirstiella pyriformis*; Mader et al. 1986). With two "oilers" and two "blotters," we were able to demite the 60 animals in less than one hour.

Acknowledgments.—We thank B. Kondratieff for the initial suggestion of using oil to kill mites. We thank our colleagues C. Carreño, T. Esque, and three anonymous reviewers for providing helpful comments on earlier versions of the manuscript. R. Espinoza was supported by a Porter Fellowship from the American Physiological Society. Chuckwallas were collected under a Nevada state permit (#96-58) granted to E. D. Brodie, Jr. and P. Ustach.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send three copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover): R. Kathryn Vaughan (lizards, amphisbaenians, crocodilians, Sphenodontia); Charles W. Painter (amphibians); or Paul A. Stone (snakes, turtles). Authors are requested to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a text-only version of the file.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1997. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 4th ed., Herp. Circ. 25:1–40; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

AMBYSTOMA MABEEI (Mabee's Salamander). **BREEDING MIGRATION.** *Ambystoma mabeei* reportedly migrates to breeding ponds from late fall through early spring (Martof et al. 1980. Amphibians and Reptiles of the Carolinas and Virginia. Univ. of North Carolina Press. Chapel Hill, 264 pp.). Hardy (1969. Bull. Maryland. Herpetol. Soc. 5:65–77) found that in North Carolina *A. mabeei* migrated to breeding sites from January to March, but little is known of the breeding phenology of this species in other parts of its range. Hardy (*op. cit.*) noted that at least some museum specimens collected in November and December from South Carolina appeared to be fully ripe, suggesting that *A. mabeei* may breed earlier in the southern part of its range. During a study of herpetofaunal communities associated with isolated ephemeral wetlands in Marion Co., South Carolina, USA, three *A. mabeei* were captured in pitfall traps as they attempted to enter the wetlands. On 11 November 1996, we captured a single adult male attempting to enter a 0.41 ha forested wetland (SVL 45.2 mm; meteorological conditions during the 24 h prior to capture were: clear skies; precipitation = 0 mm; max air temp. = 10°C; min air temp. = 1°C; mean water temp. = 13.6°C). On 12 December 1996, a single adult male was captured at the edge of a second, 0.38 ha wetland (SVL 51.0 mm; overcast skies; precipitation = 1.4 mm; max air temp. = 27°C; min air temp. = 12°C; mean water temp. = 11.2°C) and on 20 December 1996, another adult male was taken from the same wetland (SVL 45.5 mm; clear skies; precipitation = 0 mm; max air temp. = 7°C; min air temp. = -5°C; mean water temp. = 5.9°C). No additional *A. mabeei* have been captured during subsequent daily monitoring of drift fences encircling each wetland. The present findings in South Carolina provide further evidence that *A. mabeei* may breed earlier in the southern part of its range. Large breeding migrations and successful reproduction of *Ambystoma* spp. appear to be tied to appropriate rainfall and temperature conditions during a relatively narrow period (Pechmann et al. 1991. Science 253:892–895). As research at the wetlands continues we hope to determine whether the paucity of *A. mabeei* captures from these sites reflects true population densities or unfavorable environmental conditions during the 1996–97 breeding season.

EURYCEA LUCIFUGA (Cave Salamander). **REPRODUCTION**. *Eurycea lucifuga* has a broad east-west distribution in limestone regions of the eastern and central United States (western Virginia to northeast Oklahoma; Hutchison 1966. Cat. Amer. Amphib. Rept. 24:1–2). Female reproductive data are available for eastern (Appalachian) populations but are sparse for western (Ozarkian) populations. Available information consists primarily of data on larval ecology from Missouri and Oklahoma (Myers 1958. Quart. J. Florida Acad. Sci. 21:125–130; Rudolph 1978. Amer. Midl. Nat. 100:141–159), and data on maturity and clutch size from Arkansas (Trauth et al. 1990. Proc. Arkansas Acad. Sci. 44:107–113).

Sanders and Plummer collected 55 female *E. lucifuga* in monthly samples from March 1977–April 1978 from two caves in Independence Co., Arkansas (Search Cave, 9.6 km N of Batesville, and Blowing Cave, 1.6 km W of Cushman), and Sanders collected 45 females in monthly samples from July 1978–October 1979 from four nearby caves on the eastern shore of Lake Barkley in Trigg Co., Kentucky (Rimcrest Cave, River Road Cave, Taylor Bluff Cave, and Taylor Bluff Annex Cave). Herein we briefly describe reproduction in female *E. lucifuga* from each locality (Sanders 1981. M.S. Thesis, Murray State Univ., Murray, Kentucky).

In Arkansas, based on the presence of yolking follicles, size at maturity was 55–58 mm SVL. Adults averaged 58.8 mm SVL (SD = 2.09; N = 15; range 55–62.5 mm). Ova increased in diameter beginning in June and reached maximum size (3.0 mm) in August–September. Oviducts increased in width beginning in June and reached maximum width (1.1 mm) in September. One specimen in September with large oviductal follicles apparently was ready to oviposit. Large empty oviducts after September suggests that oviposition occurred in October. Clutch size averaged 73.7 eggs (SD = 18.1; N = 15) and was not correlated with SVL (r = 0.30; P>0.05). Larvae were first seen in December.

In Kentucky, size at maturity was 49–57 mm SVL. Adults averaged 56.8 mm SVL (SD = 3.86; N = 14; range 49–62.0 mm). Ova increased in diameter beginning in June and reached maximum size (2.9 mm) in July–August. Oviducts increased in width beginning in June and reached maximum width (1.2 mm) in August. One specimen in September with large oviductal follicles apparently was ready to oviposit. Large empty oviducts in eight females in September suggests that oviposition occurred in September. Clutch size averaged 75.3 eggs (SD = 33.1; N = 14) and was correlated with SVL (r = 0.88; P>0.001). Larvae were first seen in October.

Other than a slight indication that Kentucky *E. lucifuga* may oviposit earlier in the year compared to Arkansas *E. lucifuga*, our results generally suggest that, in the reproductive attributes measured, *E. lucifuga* from the two study areas were similar to one another and to other Appalachian (Hutchison 1956. Natl. Speleol. Soc. Occas. Pap. 3:10–16; Green et al. 1967. West Virginia Acad. Sci. 39:297–304) and Ozarkian populations (Trauth et al., *op cit.*). Although reproductive attributes of a species often vary geographically in wide-ranging species, these results are concordant with

NOTOTRITON ABSCONDENS (Cordilleran Moss Salamander). **REPRODUCTION.** Eggs of only three of the 13 recognized species of *Nototriton* have been reported: *N. barbouri* (McCranie and Wilson 1992. Herpetol. Rev. 23:115–116), *N. guanacaste* and *N. picadoi* (Good and Wake 1993. Herpetol. Monogr. 7:131–159).

We found a clutch of eggs in close proximity to a female *N. abscondens* on 27 May 1994 at Cascajal de las Nubes, Province of San José, Costa Rica, 1750 m elev. (Fig. 1). The clutch contained 17 eggs which adhered in a tight cluster and were not connected by thin jelly strands. Yolk diameter of formalin-preserved eggs averaged 2.7 ± 0.2 mm. Diameter of the egg capsule averaged 4.1 ± 0.3 mm. The yolk was yellowish white. The eggs were in an early stage of embryogenesis (prior to the onset of neurulation). Two of the eggs were dead when collected and the remainder died within 72 h. The female (32 mm SVL; 73 mm TL) was found adjacent to the eggs but was not exhibiting any brooding behavior such as coiling around the eggs. The ovaries contained numerous previtelligenic ova and seven partially yolked ova (ca. 1 mm diameter). One oviduct was folded and enlarged, which is consistent with the female having recently oviposited. The eggs were identified based on their proximity to this female. However their size and structure are consistent with those of other species of *Nototriton*. Because the eggs of *N. abscondens* were found at an early developmental stage, the proximity of a female cannot be taken as a sign that brooding occurs in this species.

The clutch was found on the soil surface under a mat of liverworts ca. 1.8 m above ground on a vertical road bank. The road bank faces southwest and rises ca. 2.5 m, on top of which is dense forest. The upper part of the road bank is covered by *Gunnera* and ferns that provide shade. Other salamanders occurring at this site are *N. richardi*, *Oedipina uniformis*, *O. poelzi*, *Bolitoglossa subpalmata*, and *B. robusta*.

FIG. 1. Adult female *Nototriton abscondens* with a clutch of eggs. Photographed in the laboratory 24 h after discovery.

The clutch (MVZ 225898) and female (MVZ 225897) have been deposited in the Museum of Vertebrate Zoology, University of California, Berkeley.

We thank D. Wake and P. Léon for assistance in the field, The Ministerio de Recurson Naturales, Energía y Minas for a scientific collecting permit, and F. Bolaños and the University of Costa Rica for the use of facilities. This work was supported by NSF BSR 90 19810. ELJ was supported by a predoctoral fellowship from NSF, and MGP was supported by a postdoctoral fellowship from the Ministerio de Educación y Ciencia of Spain.

Submitted by **ELIZABETH L. JOCKUSCH** and **MARIO GARCIA-PARIS**, Museum of Vertebrate Zoology and Department of Integrative Biology, University of California, Berkeley, California 94720, USA.

PLETHODON DORSALIS (Zigzag Salamander). **REPRODUCTION**. Although nesting activity has been reported for many species of eastern *Plethodon*, we are unaware of any reports of such activity in *P. dorsalis*. On 2 August 1995 we found an aggregation of *P. dorsalis* in a series of fissures situated in the clay floor of a cave located in the Central Basin (northern Rutherford County) of middle Tennessee, USA. The fissures were located near the end of the twilight zone, ca. 20 m from the mouth of the cave. Thirty-three adult *P. dorsalis*, including seven females brooding eggs, were unearthed within a m^3 of the cave floor. Clutch size ranged from 4–7 eggs; mean clutch size was not determined because we were uncertain if all clutches were intact when unearthed.

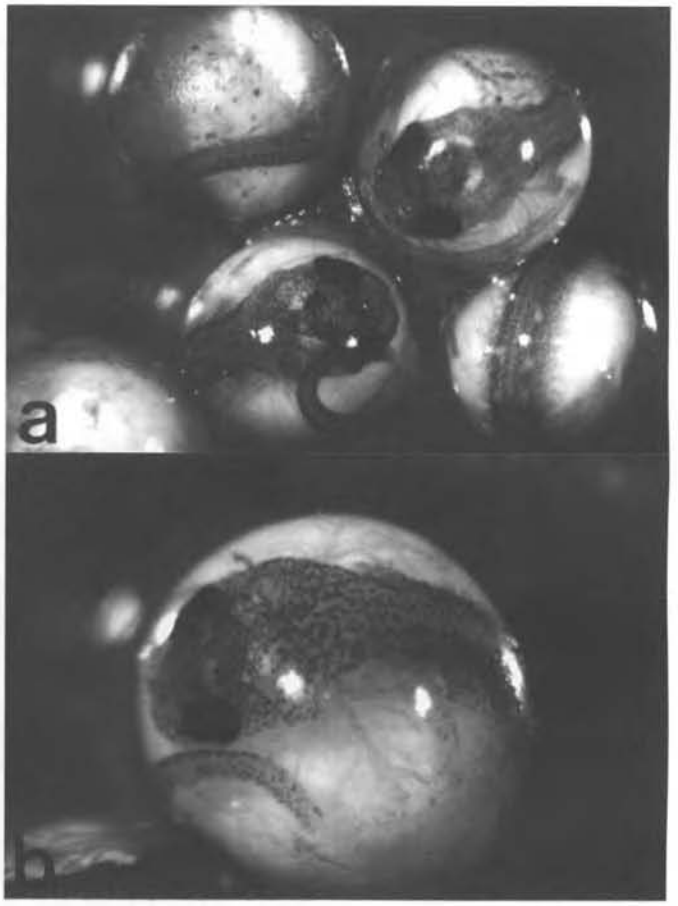

FIG. 1. Embryos of *Plethodon dorsalis* collected and photographed 2 August 1995. (A) Note body pigmentation, large yolk mass, and vascular supply to the developing gills. (B) Note faint outline of gill edge.

The yolk mass was large in all eggs, although the embryos were well developed with a mid-dorsal stripe evident on all individuals (Fig. 1). Eggs placed in an environmental chamber (12L/12D cycle; 15°C) hatched on 1 and 2 September. The developmental stage of the embryos at the time of discovery and the hatching date suggests that egg deposition occurs in early to mid June in the Central Basin. The occurrence of nest sites in the floor of a cave supports the suggestion by Smith (1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Survey, Urbana. 298 pp.) and Mount (1975. The Reptiles and Amphibians of Alabama. Auburn University. 347 pp.) that nesting in *P. dorsalis* occurs in subterranean passages or cavities rather than in logs.

GYMNOPHIONA

CHTHONERPETON INDISTINCTUM (NCN). **ALBINISM.** On 18 December 1996 an albino male *Chthonerpeton indistinctum* (SVL 265 mm; diameter 7.8 mm; ring number 77) was collected on the edge of the Parana River near Barranqueras City, Chaco Province, Argentina (27°29'S, 58°54'W) This specimen is UNNEC 05158 (Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, Corrientes, Argentina). This is the first report of albinism in this species.

Submitted by **PEDRO MATIAS CACIVIO**, Pedro Marnol 243. ANURA

ASCAPHUS TRUEI (Tailed Frog). **PREDATION.** There are few reports of predators on *Ascaphus truei*. During surveys of headwater streams on the Olympic Peninsula, we observed two instances of predation on *A. truei* on 22–23 August 1996. Both occurrences were in a SW-facing tributary of Matheny Creek, Jefferson Co., Washington, USA (T24N, R10 1/2 S, SE1/4 Sec. 12; 305 m). Water temperature was 12°C and air temperature was 14°C on both days at the start of the surveys. The surrounding forest was old growth, dominated by Douglas-fir (*Pseudotsuga menziesii*), western hemlock (*Tsuga heterophylla*), and western redcedar (*Thuja plicata*).

On 23 August, a live, metamorphosing *A. truei* was found in the mandibles of a hellgrammite (Megaloptera) in a pool in the stream. The frog was nearly transformed, having only 5 mm of tail remaining (17 mm SVL, 22 mm TL). On 22 August, we observed a Cope's giant salamander (*Dicamptodon copei*; 54 mm SVL; 107 mm TL; 10.0 g) that lunged at and bit a metamorphic *A. truei* (19 mm SVL; 23 mm TL) that hopped in front of it. When the salamander was collected, it released the frog. Although *D. copei* is cited as a major predator of *A. truei* (Leonard et al. 1993. Amphibians of Washington and Oregon, Seattle Audubon Society, Seattle, Washington. 166 pp.) and these salamanders have been documented feeding on eggs and larval specimens, we find no records of their feeding on metamorphic *A. truei* (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest, University of Idaho Press, 332 pp.).

Three species of stream-dwelling amphibians were abundant in the stream: *A. truei*, 3.6/m^2; *D. copei*, 2.8/m^2; and *Rhyacotriton olympicus*, 1.2/m^2 (density estimates from pooled data of 10 variable-width belts). Late-stage metamorphosing individuals may be more conspicuous and susceptible to predation than larvae or adults. During this time of year, metamorphosing *A. truei* may be an important food source for predators.

We thank John O'Leary and Brian Dickey for field work and Don Major and Bruce Bury for commenting on this note.

Submitted by **LAWRENCE L. C. JONES** and **MARTIN G. RAPHAEL**, USDA Forest Service, Pacific Northwest Research Station 3625 93rd Avenue SW, Olympia, Washington 98512, USA.

PHRYNOHYAS VENULOSA (Veined Treefrog, "Rana lechosa"). **ANTIPREDATOR DEVICE.** Skin secretions in the neotropical frog *Phrynohyas venulosa* have been suggested as an adaptive response to arid environments (Neil and Allen 1959. Publ. Res. Div., Ross Allen's Reptile Inst. 2:1–76). Secretions are used to line tree cavities in which these frogs seek refuge (Goeldi 1907. Proc. Zool. Soc. London. 135–140; Vellard 1948. Acta Zool. Lilloana 5:137–174), thus preventing water loss within the holes (McDiarmid 1968. Contrib. Sci. Los Angeles Co. Mus. 68:1–15). Smith (1941. Chicago Nat. 4:35–43) first suggested that the secretions are probably a deterrent to predation, a suggestion also made by other authors (Duellman 1956. Misc. Publ. Mus. Zool. Univ. Michigan 96:1–47; Neil and Allen, *op. cit*; Duellman 1970. Monogr. Mus. Nat. Hist., Univ. Kansas (1):xi + 753 pp). The following account documents an instance of the secretion acting as an antipredator device. The observation was made on 11 November 1995, between 0830–1130 h at the Universidad Central de Venezuela, Maracay, Estado Aragua, Venezuela.

A cat-eyed snake, *Leptodeira annulata ashmeadii,* was observed and photographed on a "cereza" tree (*Malpighia glabra*) partially immobilized due to the action of a viscous substance similar to that secreted by *P. venulosa*. The snake was ca. 1.5 m above ground, and was coiled on the tree trunk around the entrance of a hole 8 cm in diameter and ca. 20 cm deep. After 3 h the snake appeared exhausted from struggling and the substance had nearly

FIG. 1. *Leptodeira annulata ashmeadii* immobilized by sticky skin secretions of *Phrynohyas venulosa*.

hardened. The snake was removed and held in captivity. After 24 h in captivity, the snake appeared to have recovered, and after 10 days it was sacrificed, preserved, and deposited in the Museo del Instituto del Zoología Agrícola, Facultad de Argonomía, Universidad Central de Venezuela, Maracay (MIZA 521).

Phrynohyas venulosa is common in this area (Manzanilla et al. 1995. Acta Científica Venezolana 46[3]:1–9) and the tree hole where the snake was found and similar nearby tree holes have been observed as shelters that are often used by this frog. (e.g., MIZA 319, 524). Although we did not observe a frog depositing skin secretions around this particular tree hole, the similarity in appearance to secretions of *P. venulosa* and our previous observations of frogs at this site support our conclusion that the material encountered by the *Leptodeira* was indeed produced by a *P. venulosa*. The secretion may have the dual function of decreasing water loss within the cavity inhabited by the frog, as well as being an effective device against potential predators. Other than being immobilized, we observed no ill effects to the snake.

We extend our gratitude to Dr. Alberto Fernandez-Badillo (Instituto de Zoología Agrícola, UCV, Maracay) for identifying the frog and snake.

Submitted by **JESUS MANZANILLA**, Estación Biológica "Dr. Alberto Fernández Yépez," Facultad de Argonomía, Universidad Central de Venezuela, Apartado 4579, Maracay 2101-A, **ENRIQUE LA MARCA**, Universidad de los Andes, Escuela de Geografía, Laboratorio de Biogeografía, Apartado 116, Mérida 5101-A, and **OSVALDO VILLAREAL** and **DINORA SANCHEZ**, Facultad de Agronomía de la Universidad Central de Venezuels, Maracay, Venezuela.

RANA CAPITO SEVOSA (Dusky Gopher Frog). **PREDATION.** At 1200 h on 10 May 1997, we collected an adult female banded water snake, *Nerodia fasciata*, (SVL 69.7 cm; tail 21.3 cm) at Salt Pond in the Conecuh National Forest Wildlife Management Area, Covington Co., Alabama, USA, that regurgitated two intact and two partially digested *Rana capito sevosa* tadpoles; one was preserved (AUM 34164).

Salt Pond is a fishless, ephemeral sinkhole (<1 ha) and one of the few known remaining breeding sites of *R. c. sevosa* in southern Alabama (C. Guyer, pers. comm.). This species breeds almost exclusively in fishless ponds and the introduction of predatory fishes appears to eliminate populations at these ponds (Mount 1980. Survey for the Presence or Absence of Threatened or Endangered Reptiles and Amphibians, Conecuh National Forest, Alabama. Unpubl. Rept., U.S. Forest Service. 108 pp.). Bailey (1989, unpubl. M.S. thesis, Auburn University. 56 pp.) observed caddisfly larvae and an adult central newt, *Notophthalamus viridescens louisianensis*, feeding on egg masses of *R. c. sevosa*. There are no reported observations of predation on tadpoles. Our observations suggests that *N. fasciata* may be an important natural predator of *R. c. sevosa* tadpoles.

RANA CATESBEIANA (Bullfrog). **DIET.** Bullfrogs and green frogs (*Rana clamitans*) live sympatrically throughout much of their range (Conant and Collins 1991. Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). Consumption of post metamorphic *R. clamitans* has been documented in studies of bullfrog diets (Bury and Whelan 1986. Ecology and Management of the Bullfrog. U.S. Fish and Wildlife Service Resource Publication 155. 24 pp. and references therein). However, no one has reported *R. clamitans* tadpoles in the diet of *R. catesbeiana*. This was assumed by Fulk and Whitaker (1969. Proc. Indiana Acad. Sci 78:491–496) but due to the difficulties in identifying tadpoles from bullfrog stomach contents, it has never been verified.

In laboratory experiments, we found *R. catesbeiana* consume both *R. clamitans* and conspecific tadpoles and show no preference between them ($P = 0.09$). Tadpoles and frogs were collected in October 1996 using seines and hand nets. Bullfrogs were collected in Woo Pond on the western border of Cheshire Township in New Haven Co., Connecticut, and green frogs were collected in Dentist Marsh in the Yale-Myers Research Forest near Union, Tolland Co., Connecticut, USA. Three adult *R. catesbeiana* were kept in separate 37.8 L aquaria and given earthworms *ad libidum*. One hundred fifty *R. clamitans* tadpoles (Gosner stage 25–29; mean 3.8 ± 0.9 g) were kept in eight 18.9 L containers. Forty *R. catesbeiana* tadpoles (Gosner stage 25–29; mean 13.5 ± 2.4 g) were kept in two 124.9 L containers. Both were fed crushed rabbit pellets and fish food. Three foraging experiments were conducted in containers (14 x 35 x 50 cm) that were filled with 8.4 L of water to a depth of 4 cm. There were three replicated containers and one control for each experiment. The control containers lacked adult *R. catesbeiana* and contained the same number and type of tadpoles as the experimental containers. Different tadpoles were used in each experiment. All tadpoles survived in the control containers. The experiments were monitored at the same time each day for five days.

In the first experiment, 10 *R. clamitans* tadpoles and one adult *R. catesbeiana* were placed in each box. On average, the *R. catesbeiana* consumed 1.3 ± 0.83 tadpoles per day. The second experiment was conducted in a similar manner with three *R. catesbeiana* tadpoles. On average, 0.6 ± 0.23 *R. catesbeiana* tadpoles were eaten per day. In the third experiment, three *R. catesbeiana* tadpoles, three *R. clamitans* tadpoles, and one adult *R. catesbeiana* were placed in each container. Both species of tadpoles were eaten (Manly's alpha preference: 0.56 for *R. clamitans* tadpoles and 0.44 for *R. catesbeiana* tadpoles). *Rana clamitans* tadpoles were taken at an average rate of 0.6 ± 0 per day and *R. catesbeiana* tadpoles at an average rate of 0.4 ± 0.23 per day.

We thank David Skelly and Joseph Kiesecker for their advice and for reviewing earlier versions of this manuscript. This research was supported by the Sperry-Carpinter Fund.

TESTUDINES

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **COPULATION.** Carr and Carr (1986. Herpetol. Rev. 17:24–25) observed a pair of *Dermochelys coriacea* copulating near Culebra Island, Puerto Rico. We report a second observation of copulation for this species near Suriname. At Matapica Beach, Suriname, on 24 June 1994 at ca. 1600 h, we observed two *D. coriacea* ca. 30 m offshore, one on top of the other. The upper turtle was clutching the lower turtle with its front flippers. The lower turtle was completely submerged, and was heard taking deep breaths at regular intervals. We do not know how long the turtles had been together before we noticed them. After ca. 20 min, the upper turtle shook loose and swam away underwater, while the lower turtle remained quiescent at the surface. After another 10 min, it began swimming on the surface, parallel to the beach.

From local fisherman and conservation workers, we learned that copulating *D. coriacea* are not an uncommon sight in the waters near this nesting beach. Eckert and Eckert (1988. Copeia 1988:400–406) used data on the distribution of epibionts on the carapaces of female *D. coriacea* to infer that turtles nesting in St. Croix must have mated outside of tropical waters. In contrast, our observations demonstrate that these turtles do mate in tropical waters. It may be that *D. coriacea* in Suriname have different mating patterns from those in St. Croix.

We thank Peter Dutton for encouragement and Marc Girondot for comments. Funding was provided by the Natural Sciences and Engineering Council of Canada (to N. Mrosovsky).

LACERTILIA

ANOLIS NITENS CHRYSOLEPIS (Goldenscale Anole). **PREDATION**. *Anolis nitens chrysolepis* is a medium-sized lizard of the family Polychrotidae, reaching 75 mm SVL. This diurnal, nonheliophilic and terrestrial lizard is an inhabitant of the forests of NE South America

On 20 November 1996 at 0930 h, while searching for amphibians in the region of Saul in French Guiana, ca. 8 km from the village, not far from "Montagne Belvédère" (3°36'N, 53°10'W), we observed a whip spider, *Heterophrynus longicornis* Butler (Arachnida, Amblypigi), eating a juvenile *Anolis nitens chrysolepis* (preserved, IRSNB n° 14576) headfirst. Measurement of the remainder of the lizard's body suggested a SVL of ca. 35 mm. The *Heterophrynus* and its prey were in a vertical, rotting stump 30 cm above the ground, in primary forest near a small stream. The weather was dry; the temperature and relative humidity in the stump were 29°C and 87%, respectively

Known predators of *A. nitens* include the snakes *Oxybelis aeneus, O. argenteus*, and *O. fulgidus* (Avila–Pires 1995. Lizards of Brazilian Amazonia, Zoologische Verhandelingen 299:86–87, Leiden). Whip spiders are nocturnal and are known to prey on invertebrates (we observed specimens eating small crickets at night). We believe that this is the first observation of predation on a lizard. It is interesting to note that males of *Gonatodes annularis* (Gekkonidae) often are encountered in stumps or tree trunks inhabited by whip spiders, and that they often have scars. It is possible that *Heterophrynus longicornis* also prey on this and other small lizard species.

ANOTOSAURA BRACHYLEPIS (NCN). **PREDATION.** *Anotosaura brachylepis* is a microteiid known onty from the Serra do Cipó range in Minas Gerais, southeastern Brazil (19°20'S, 43°44'W). This lizard reaches 61 mm SVL and 200 mm in total length. It occurs in montane fields, is regarded as a rare species (Dixon 1974. Herpetologica 30:13–18), and appears to be fossorial (I. Sazima, pers. comm.). However, except for systematic studies on the genus (Amaral 1933. Mem. Inst. Butantan 7:53–74; Dixon 1973. Univ Kansas Mus. Nat Hist. Misc. Publ. 57:1–47; Dixon, *op. cit.*), no additional information is available.

During a study of the feeding habits of *Tropidurus montanus* (Tropiduridae) in the Serra do Cipó, I found a juvenile *A. brachylepis* (30 mm SVL, 92.7 mm TL) in the stomach of an adult female *T. montanus* (71.7 mm SVL, 152 mm TL, 10.5 g). The body of the prey was broken into two parts, and the tail was in four pieces, but all of these were intact and undigested. Insects also were found in the stomach. *Tropidurus montanus* is sympatric with *A. brachylepis* in the Serra do Cipó. Predation on this microteiid by *T. montanus* probably is opportunistic, since the latter seems to be omnivorous (pers. obs.). The two lizard specimens are deposited in the Museu de Historia Natural da Universidade Estadual de Campinas: *T. montanus* (ZUEC 01967) and *A. brachylepis* (ZUEC 01968).

I thank I. Sazima for the identification of *A. brachylepis* and for reading the manuscript.

CHAMELEO OWENI (Owen's Chameleon). **REPRODUCTION.** On 13 August 1995 a female *Chameleo oweni* was collected in the Southwestern Province of Cameroon, near Nguti. The specimen was in the process of digging a hole when found. The following day the specimen oviposited 9 eggs. The eggs were placed in a small container with moist humus until their arrival at the University of Texas at Arlington on 14 December 1995. Upon arrival all of the eggs appeared to be in good condition except for one that had decomposed. Eight eggs were measured (mean size 17.56 mm x 11.03 mm). The eggs were then incubated in a 1:1 mixture of vermiculite and water. The incubation temperature was maintained at 28°C. Eight neonates hatched (mean SVL = 31.5 mm, TL = 44.6 mm, 0.68 g) after an incubation period of 155 days. Nothing is known regarding the reproductive behavior of this species in the wild.

My thanks to Jonathan A. Campbell for his encouragement and support of this project, Dwight P. Lawson for providing the specimens for this study, and the staff of the Dallas Zoo Department of Herpetology for all of their helpful comments and review of this manuscript.

HEMIDACTYLUS MABOUIA (Tropical House Gecko). **CANNIBALISM**. *Hemidactylus mabouia* is an exotic gekkonid presumably introduced via slave ships to Brazil (Vanzolini 1978. Papéis Avulsos Zool., S. Paulo 31(20):307–343). We report an instance of cannibalism in this species. On 15 March 1997 we examined the stomach contents of 67 specimens of this gecko (62 of the stomachs contained food) collected in a pasture near Pontal do Ipiranga, municipality of Linhares, Espírito Santo, eastern Brazil (ca. 19°19'S, 39°43'W, near sea level). One adult male (43.2 mm SVL, 2.7 g) had in its stomach a conspecific juvenile with a broken tail (21.9 mm SVL, 0.4 g), ingested headfirst. Conspecific prey occurred with 1.6% frequency in our samples. Low incidence of cannibalism has been observed in other lizard species, and opportunistic foraging has been regarded as the main explanation for occasional cannibalism in lizards (Polis and Myers 1985. J. Herpetol. 19:99–107; Rocha 1992. Herpetol. Rev. 23:60). Specimens were deposited in the Coleção Zoológica da Universidade Federal do Espírito Santo. CZ thanks the PICDT/CAPES for a fellowship grant, and RLT thanks the CNPq for a post-doctoral grant (Proc. No. 302657/87-8).

MABUYA QUINQUETAENIATA QUINQUETAENIATA (Bean Skink). **FORAGING.** On 6–7 July 1996, I observed *Mabuya q. quinquetaeniata* in Lake Nasser, Egypt. This skink is common throughout Egypt's Nile River Valley (Marx 1968. Checklist of the Reptiles and Amphibians of Egypt. USNMRUN 3, Cairo), and can be found actively foraging through leaf litter and grasses (pers. obs.). Skinks were active by 0800 h on the rocky banks of the lake, in close proximity to the water (<1 m). Dragonflies were particularly abundant within 1 m from the edge of the water. An adult *Mabuya q. quinquetaeniata* would wait motionless for extended periods of time until a dragonfly hovered slightly above it, after which the skink would jump into the air and pull down its prey. If the dragonfly was too high, the skink would stand in a tripod position to lessen the distance between itself and its prey, and then jump. This behavior was seen among many of the larger adults. Thus, *Mabuya q. quinquetaeniata* exhibits both active and sit-and-wait foraging behaviors, like some New World species of *Mabuya* (Vitt 1991. J. Herpetol. 25:79–90; Vrcibradic and Rocha 1996. J. Herpetol. 30:60–67).

SCELOPORUS BELLI (Bell's Spiny Lizard). **PATTERN.** *Sceloporus belli* is unusual in the genus in having strong dimorphism in dorsal pattern. Mature males are essentially unicolor except for a broad dorsolateral light line bordering a broad lateral dark (brown) line below which lies a distinct lateral light line separated from the blue abdominal semeions by a narrow, indistinct brownish line. On the contrary, in females the dorsolateral light lines are obscured by a series of somewhat chevron-shaped black transverse marks extending from a paravertebral area across each dorsolateral light line; furthermore the lateral area is variegated light and dark, not stripe-like; the lateral light line is interrupted by numerous black streaks, and the sublateral area blends with the essentially unmarked abdomen.

As in most other species of *Sceloporus*, and in all other taxa of the *undulatus* group except *S. virgatus*, males also regularly differ from females in possessing conspicuous gular and/or abdominal semeions. In *S. belli* there is a single, median blue patch on the throat and an elongate pair on the sides of the abdomen. The latter pair is black-bordered medially, as in most other taxa of the *undulatus* group, but black is usually absent in the gular region (present in most other taxa). Also, as in most other species of the genus, and in all of its group, there is a pair of enlarged postanal scales in males (presumably serving to help anchor the hemipenes), but none in females.

However, as noted in the original description of *S. belli* (Smith et al. 1995. Texas J. Sci. 47:124), some males have the female dorsal pattern. One such specimen (University of Colorado Museum 58593) was taken 3 July 1996, basking at the top of Cerros Colorados (ca. 22 air km SE Samalayuca), Chihuahua, Mexico, by one of us (JAL-E). We have noted six other female mimics, all in the Museum of Southwestern Biology and all from the state of Chihuahua, as follows: 39947, Ojo de los Reyes, 4.7 km SE Galeana, 1 mi N Angostura, 12 May, 1977; 35043, 35045, 15 km E, 7 km N San Buenaventura, Hy 10, 19 June 1971; 8961, 8966, 3 mi S El Sueco, Hy. 45, 2 August 1962; and 56335, jct Hy 16 and 45, just SW Cd. Chihuahua, 7 August 1975. These five localities are scattered over a 310 x 140 km span of the northern central part of the state. The mimics may occur elsewhere, but are not represented among the 70 specimens, about half males, in the UCM collection from as far north as 15.6 km S Cd. Chihuahua and southward into Durango. We have not re-examined material from elsewhere (e.g., southern Coahuila, northern Zacatecas).

All seven mimics are sexually mature, even though some were noted as "young" in the original description. The smallest two, at 52 and 56 mm SVL, taken in May and June, respectively, have well-developed gonads, totalling 3.4 and 4.0% respectively of the gross body weight, typical of breeding males. The largest specimen, 74 mm SVL, also taken in June, has gonads totalling 2.2% of the body weight. The other four (taken in July and August) are 63–68 mm in SVL, and are therefore presumably sexually mature although their gonads totalled only 0.2–0.4% of the body weight, having regressed greatly from the active reproductive state.

In addition, a single testis was removed, sectioned (10 µm) and stained (hematoxylin/eosin) from each of the seven mimics. Active sperm production was evident in the three specimens taken in May and June. The regressed testes of the four taken in July and August showed no such activity, as expected, although residual sperm were noted in the epididymis of one animal. Thus there is no question that the mimics with the female dorsal pattern were functional males, not sterile as an adjunct of the female dorsal pattern.

Certain variations in male coloration of various sceloporine lizards are well known to reflect reproductive behavior. Examples include *S. undulatus erythrocheilus* (Rand 1997. Anim. Behav., ms. submitted), *Urosaurus ornatus* (Thompson and Moore 1991. Anim. Behav. 42:745–753), and *Uta stansburiana* (Sinervo and Lively 1996. Nature 380:240–243). Each of these taxa exhibits different throat colors and/or patterns that signal social status and, consequently, behavior, in a subordinate-dominant continuum. These patterns are all honest signals, however, presumably used in the assessment of fighting ability in aggressive interactions.

In both lizards (Cooper 1984. Anim. Behav. 32:1142–1150) and sunfishes (Stacey and Chiszar 1978. Behaviour 64:271-297), female coloration has been shown to decrease aggression among males. No cases have yet been documented in lizards of males adopting female coloration in avoidance of aggression.

In sunfishes, female mimics enter nests of territorial males and fertilize eggs deposited there (Dominey 1980. Nature 284:546–548). Gross (1982. Z. Tierpsychol. 60:1–26) described two alternative male phenotypes in the bluegill sunfish (*Lepomis macrochirus*): sneakers and satellites. Both cuckolded territorial males, but satellites had female coloration and sneakers did not. Sneakers were regularly attacked by males and satellites were not, presumably due to female mimicry.

That female mimicry can reduce aggressive behavior in lizards was demonstrated experimentally by Cooper (*loc. cit.*), who painted male *Holbrookia propinqua* with female coloration and introduced them into the territory of unaltered males. These artificial female mimics were not attacked, and in fact were courted by resident males. Thus in *S. belli*, female mimicry may be an alternative male reproductive tactic for non-territorial males to cuckold territorial males.

On the other hand, the significance of female mimicry in some male *S. belli* may lie strictly in its phylogenetic origin, with no reproductive exploitation. The dorsal pattern of female *S. belli* is basically the same as that in both sexes of most other members of the *undulatus* group of *Sceloporus*: a paravertebral series of dark spots or transverse streaks bordering medially a pair of dorsolat-

eral light lines, which are interrupted by the paravertebral streaks in some taxa (as in *S. belli*), not in others, in which they may be reduced to small spots. The sides are marked much like the dorsum.

It is the male *S. belli* that differs from the general rule of sexually indistinguishable dorsal pattern, in its loss of dorsal markings and development of a dark lateral stripe. The occasional appearance of the female dorsal pattern in male *S. belli* might be merely a paedotypic retention of the ancestral markings characteristic of both sexes in all subspecies of *S. undulatus* (Reilly et al. 1997. Biol. J. Linn. Soc. 60:119–143). It may, for that reason, be geographically limited, perhaps in the area of closest contact with its possible ancestral relative, *S. u. consobrinus* (Smith et al., *loc. cit.*).

The only other member of the *undulatus* group with distinct sexual dimorphism in dorsal pattern is *S. woodi*, a diminutive species of Florida with basically the same modification of the male dorsal pattern as in *S. belli*. Whether occasional males of that species have the typical female dorsal pattern, as in *S. belli*, is unknown.

We are much indebted to Drs. Richard E. Jones, Jeffrey Mitton, and David O. Norris for invaluable counsel; to Donald Scott Sias for the loan of the vital specimens in the Museum of Southwestern Biology; and to Drs. Carl Bock, Michael Grant and Shi Kuei Wu for space and facilities for study.

SCINCELLA LATERALIS (Ground Skink). **AQUATIC BEHAVIOR.** Escape behaviors, such as retreat to refugia (Brooks 1967. Ecol. Monogr. 37:71–87) and tail autotomy (Dial and Fitzpatrick 1983. Science 219:391–393), have been reported for *Scincella lateralis*. We report here observations of escape into an aquatic habitat by this chiefly terrestrial species.

During a field collection of this species at Thistlewaite Wildlife Management Area (St. Landry Parish, Louisiana, USA), we witnessed several instances of aquatic behavior in adults and juveniles in a population of ground skinks. The general habitat of the collecting area is bottomland forest dominated by water oak (*Quercus nigra*) and palmetto (*Sabal minor*) in high areas, and by bald cypress (*Taxodium distichum*) and tupelo (*Nyssa aquatica*) in low areas. Standing water occurs in both elevations, of which the lower portions are usually flooded. On 23 March 1997 from 1400–1500 h CST, we followed a path along a small gravel levee in search of ground skinks. Numerous lizards were sighted on the slopes of the levee, which at first bordered dry oak-palmetto forest, but further along bordered cypress-tupelo swamp. Typically, ground skinks attempted to avoid capture by dashing to underground retreats in the gravel bed of the levee. However, upon our approach an adult of unknown gender was observed to run without hesitation into the swamp and swim to a branch over 1 m out; the water depth was ca. 0.5 m. We later observed another adult (sex unknown), as well as a juvenile, swim across shallow water to evade capture. Finally, a female was observed to dive under water and reappear shortly afterwards with only its head peeking out from the surface. This female (45 mm SVL) was subsequently collected *in aquatica*.

During none of the swimming events that we observed did the lizards appear challenged by the aquatic habitat. Indeed, the ground skinks were adept swimmers and utilized lateral undulations of their elongate bodies for propulsion through the water. Aquatic behavior has also been documented in other lizards: *Cnemidophorus sexlineatus* (Trauth et al. 1996. Herpetol. Rev. 27:20–21) and *Tupinambis teguixin* (Olmos 1995. Herpetol. Rev. 26:37). *Scincella lateralis* is notoriously difficult to capture (Lewis 1951. Am. Midl. Nat. 45:232–240) and the aquatic escape behavior appears to be a strategic asset in habitats where standing water is not uncommon, such as the lowland regions of southern Louisiana.

We thank the Louisiana Department of Wildlife and Fisheries for granting both access to Thistlewaite Wildlife Management Area and permission to collect lizards (permit LNHP-97-025 to JAA).

SERPENTES

AGKISTRODON PISCIVORUS PISCIVORUS (Eastern Cottonmouth). **PREDATION.** Predation on juvenile *Agkistrodon piscivorus* by vertebrates is well documented (Ernst 1992. Venomous Reptiles of North America. Smithsonian Institution Press, Washington, D.C., 275 pp.; Mitchell 1994. Reptiles of Virginia. Smithsonian Institution Press, Washington, D.C., 352 pp.). Here we document the first case of predation on *A. p. piscivorus* by an invertebrate, the ghost crab (*Ocypode quadrata*).

At 0900 h on 15 October 1996, we observed a juvenile *A. p. piscivorus* (ca. 275 mm TL, with sulfur-yellow tipped tail) in the right claw of an adult *O. quadrata* at Back Bay National Wildlife Refuge (BBNWR), Virginia Beach, Virginia, USA. The snake initially might have been seized just posterior to the head; the skin and musculature in this area were mutilated. However, when the crab was first spotted the still-living snake was being held by the lower jaw. The *O. quadrata* dragged the snake into the vegetation atop a sand dune and disappeared.

Ocypode quadrata is both an opportunistic scavenger and an effective predator (Herreid and Full 1988. Energetics and Locomotion. *In* Burggren and McMahon, eds., Biology of the Land Crabs. Cambridge Univ. Press, New York. 479 pp.). At BBNWR, *A. p. piscivorus* generally is found in open water or marsh habitats, whereas *O. quadrata* is restricted to dune and beach habitats; therefore, predation on *A. p. piscivorus* by *O. quadrata* most likely is limited to chance encounters when *A. p. piscivorus* enters the habitat of *O. quadrata*.

Submitted by **CHAD L. CROSS**, Department of Biological Sciences, Old Dominion University, Norfolk, Virginia 23529-0266, USA, and **CHARLES MARSHALL**, Back Bay National Wildlife Refuge, 4005 Sandpiper Road, Virginia Beach, Virginia, 23456, USA.

ANILIUS SCYTALE (False Coral Snake). **DIET.** In June 1976, O. R. Cunha and F. P. Nascimento collected an adult male (365 mm SVL) *Anilius scytale* from Curupati-Viseu, Para, Brazil; this specimen was deposited in the Museu Paraense Emílio Goeldi (MPEG 12326). We examined the stomach contents of this specimen and found an adult male *Tantilla melanocephala melanocephala* (MPEG 19132, 190 mm SVL). *Anilius scytale*

has been reported to eat species of *Amphisbaena, Aulura,* and *Leposternon*, as well as earthworms (Cunha and Nascimento 1993. Bol. Mus. Para Emílio Goeldi 9:19–20; Duellman 1990. *In*: A. H. Gentry [ed.], Four Neotropical Rainforests, pp. 455–505. Yale Univ. Press, New Haven, Connecticut). We believe that this is the first report of *A. scytale* eating a colubrid snake.

Submitted by **FRANCISCO VALLS-MORAES**, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, Butantan, CEP: 05503-900, São Paulo, SP, Brazil, and **RUBENS NOBUO YUKI**, Museu Paraense Emílio Goeldi, Caixa Postal 399, CEP: 66040-170, Belem, PA, Brazil.

CORALLUS HORTULANUS (Deer Snake). **PREDATION.** *Corallus hortulanus* (formerly *C. enydris*; see McDiarmid et al. 1996, J. Herpetol. 30:320–326) is an arboreal species that occurs in forests and river valleys in tropical South America. This snake is nocturnal, and records on its foraging behavior in the wild are scarce. Its diet includes frogs, small rodents, bats, and birds (Cunha and Nascimento 1978. Mus. Par. EmÌlio Goeldi, Publ. Avul. 31, 218 pp.). Here, we report a bird taken in the wild by *C. hortulanus* at the Reserva Biológica de Poço das Antas (22°30'S 42°19'W), ca. 130 km northeast of Rio de Janeiro, Brazil.

On 11 October 1995 (1630 h), while checking the nest of a white-bearded manakin (*Manacus manacus*: Passeriformes: Pipridae), we noticed the female was absent. The nest was 1.1 m above the ground and contained two eggs. Nearby, we discovered an adult female *C. hortulanus* twisted around the branch the nest sat on, at about the same height as the nest. The snake had a remarkable swelling in its abdomen which proved to be the female manakin (Fig. 1). The bird had been swallowed head first and was nearly intact (with many of its feathers still dry), indicating it had been recently eaten. The snake measured 49.8 cm SVL (62 cm total length), and weighed 22.5 g (excluding prey). The prey weighed 17 g immediately after being removed from the snake's stomach. We found no other food items in the snake's digestive tract. We deposited the snake at the Museu Nacional do Rio de Janeiro (MNRJ 4784).

FIG. 1. Size relation between the predator, *Corallus hortulanus*, and its prey, *Manacus manacus*.

We thank Dionízio M. Pessamílio, Whitson José da C. Júnior, and the other officers of Reserva Biológica de Poço das Antas for logistical support. Carlos F. D. Rocha and Monique Van Sluys commented on this note and provided additional information. Ivandy N. Castro Astor and Jozélia M. S. Correia received student fellowships from the Coordenaçao de Aperfeiçoamento do Ensino Superior and CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico) respectively. CNPq provided a research grant (process no. 301524/88-2) to Maria Alice S. Alves.

FARANCIA ERYTROGRAMMA ERYTROGRAMMA (Rainbow Snake). **EGGS**. Data on clutch and egg size in *Farancia erytrogramma* consist of scattered anecdotes. Collectively, these data suggest that eggs are laid from June to August, that clutch size ranges from 20–52 eggs, and that egg dimensions range between 25.8–38.6 mm in length and 25.4–29 mm in width (Palmer and Braswell 1995. Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill. 412 pp.). Here, we add to this data base by presenting information on two other clutches.

On 20 July 1972 a female *F. erytrogramma* collected near the Ogeechee River in Chatham County, Georgia, USA, deposited 30 eggs. This snake was captured in early July, and was not weighed prior to egg deposition. Egg length was 32.26 ± 1.618 mm (mean ± SE; range = 29.90–37.00 mm); egg width was 20.92 ± 0.604 mm (mean ± SE; range = 19.60–22.10 mm), and egg mass was 7.87 g. ± 0.595 g (mean ± SE; range = 6.715–8.809 g). One noteworthy feature of these eggs was that eight pairs of eggs were attached by a thread-like strand.

Another Chatham County snake collected on 30 April 1996 near the Little Ogeechee River laid 17 eggs on 30 June. The weight of the female was 234 g after deposition. Egg length was 29.07 ± 1.944 mm (mean ± SE; range = 26.80–33.61 mm), and egg width was 17.57 ± 1.048 mm (mean ± SE; range = 14.68–18.82 mm). Unfortunately, this clutch of eggs was not weighed. As in the 1972 clutch, a single, thread-like strand attached one pair of eggs.

Submitted by **ROBERT A. MOULIS** and **GERALD K. WILLIAMSON**, Savannah-Ogeechee Canal Museum & Nature Center, 681 Fort Argyle Road, Savannah, Georgia 31419-9239, USA.

HETERODON SIMUS (Southern Hognose Snake) **DIET.** Natural food records for the southern hognose snake (*Heterodon simus*) are scarce. The species has been reported to feed primarily, if not exclusively, upon anurans (Ashton and Ashton 1981. Handbook of Reptiles and Amphibians of Florida. Part 1, The Snakes. Windward Publishing, Inc., Miami. 176 pp.; Mount 1986. *In* Mount [ed.], Vertebrate Animals of Alabama in Need of Special Attention, pp. 34–35, Alabama Agr. Expt. Sta., Auburn Univ., Alabama). Palmer and Braswell (1995. Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill, North Carolina, 412 pp.) reported only two food records for wild *H. simus* in North Caro-

lina; both were eastern spadefoot toads (*Scaphiopus holbrookii*). Here, we report three observations of stomach contents in *H. simus*, including two species previously unrecorded in this snake's diet.

A hatchling female *H. simus*, found DOR (10.3 km W of Wagram, Scotland Co., North Carolina, USA) by J. C. Beane and T. J. Thorp on 5 October 1996, contained the remains of an adult six-lined racerunner (*Cnemidophorus s. sexlineatus*). The snake (ca. 180 mm TL; 157 mm SVL) was badly mangled. The lizard was too badly fragmented for measurement, but its total length may have equaled or exceeded that of the snake. Both were deposited in the North Carolina State Museum of Natural Sciences (NCSM 44810). A second *H. simus* (NCSM 45195), also a hatchling female (170 mm TL, 148 mm SVL) found DOR (4.2 km NNW of Old Hundred, Scotland Co., North Carolina, USA) by J. C. Beane and D. A. Jackan on 24 October 1996, contained remains of a subadult *C. s. sexlineatus* and a subadult ground skink (*Scincella lateralis*). A third specimen (NCSM 39554), an adult male (380 mm TL, 303 mm SVL) found DOR (9.8 km W of Wagram, Scotland Co., North Carolina, USA) by J. C. Beane and T. J. Thorp on 8 October 1995, contained the remains of an adult *S. holbrookii*.

Lizards, including *Cnemidophorus*, have been reported as prey of *H. nasicus* and *H. platirhinos* (Platt 1969. Univ. Kansas Publ. Mus. Nat. Hist. 18:253–420). Weaver (1965. Bull. Florida State Mus. Biol. Sci. 9:275–304) reported a second-hand observation of a fence lizard (*Sceloporus undulatus*) that was killed by the bite of a *H. simus*, but that account did not indicate whether the snake actually ate the lizard, or under what circumstances the bite occurred. To our knowledge, our observations represent the first published records of reptiles as natural prey of *H. simus*.

Observations were made as a result of "Project Simus," for which partial funding was provided by a grant from the North Carolina Herpetological Society.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 29555, Raleigh, North Carolina 27626-0555, USA, **THOMAS J. THORP**, Three Lakes Nature Center and Aquarium, 400 Sausiluta Drive, Richmond, Virginia 23227, USA, and **DALE A. JACKAN**, 4801 Metcalf Drive, Raleigh, North Carolina 27612, USA.

LEPTODEIRA ANNULATA (Banded Cat-Eyed Snake). **SEXUAL DIMORPHISM**. An adult male specimen (470 mm SVL) of this species, probably originating from South America, based on its color pattern (Natural History Museum of Lyon or Musée Guimet, Lyon, France: MG 42002026; "Sumatra," obviously in error) displays numerous thin tubercles on its chin. These tubercles are present on chin scales, infralabials, and gulars. Such sexually dimorphic tubercles were previously not reported for this genus (Duellman 1958. Bull. Am. Mus. Nat. Hist. 114[1]:1–152; Shine 1993. *In* R. A. Seigel and J. T. Collins [eds.], Snakes: Ecology and Behavior, pp. 49–86. McGraw-Hill, New York).

We extend our gratitude to Joël Clary (curator of the Musée Guimet collections) for the loan of the specimen.

Submitted by **IVAN INEICH** and **PATRICK DAVID**, Muséum national d'Histoire naturelle, Laboratoire de Zoologie (Reptiles & Amphibiens), 25 rue Cuvier, F-75005 Paris, France. e-mail (II): ineich@cimrs1.mnhn.fr.

LIOPHIS MILIARIS (Common Water Snake). **PREY.** *Liophis miliaris* is known to prey on anurans (Martins et al. 1993. Amphibia-Reptilia 14: 307–309; Michaud and Dixon 1989. Herpetol. Rev. 20:39–41; Vitt 1983. Herpetologica 39:52–66) and fishes (Marques and Souza 1993. Rev. Brasil. Biol. 53:645–648; Michaud and Dixon, *op. cit.*). At 1000 h on 25 February 1994, we collected a small *L. miliaris* (221 mm SVL, 56 mm tail length, 8.99 g) at llha do Mel, Paranaguá Municipality, Paraná, Brazil (48°20'W; 25°30'S). The snake was moving on the ground in a mangrove-forested transitional area. Immediately after collection, the snake regurgitated an adult gymnophthalmid lizard, *Placosoma glabellum* (31 mm SVL, 0.5 g). The lizard had been swallowed head first, and comprised ca. 5.6% of the snake's mass. The lack of digestive activity indicates that it had been swallowed recently. Both specimens were deposited at the Universidade Estadual de Londrina herpetological collection (*L. miliaris* = CZUELHP.199; *P. glabellum* = CZUELHP.200). Identifications were verified by Julio Cesar de Moura-Leite. This is the flrst report of a wild *Liophis miliaris* feeding on a lizard.

Submitted by **REGINALDO ASCÊNCIO MACHADO, PAULO SÉRGIO BERNARDE**, Universidade Estadual de Londrina, Departamento de Biologia Animal e Vegetal, P.O. Box 6001, 86051-970, Londrina, Paraná, Brazil, and **SÉRGIO AUGUSTO ABRAHÃO MORATO**, Companhia Paranaense de Energia, Coordenadoria de Engenharia Ambiental, Rua Voluntarios da Pátria, 233, 8° andar, 80020-942, Curitiba, Paraná, Brazil.

MICRURUS DIASTEMA and ***M. LIMBATUS*** (Diastema Coral Snake and Tuxtlan Coral Snake, respectively). **DIET.** *Micrurus diastema* (N = 7) and *M. limbatus* (N = 4) were kept in captivity (southern Veracruz, México) for 24 mo, during which time they were offered 15 local species of snakes as prey, with each coral snake being offered each prey species 2–6 times. Prey were offered once per week to each coral snake. Snakes offered as prey were always alive and shorter than the coral snakes and were left with the latter for a maximum of 24 h. Consistent with Roze (1996, Coral Snakes of the Americas: Biology, Identification and Venoms. Krieger Publ., Malabar, Florida), four species were always accepted promptly: *Geophis semidoliatus, Ninia diademata, N. sebae,* and *Sibon sartorii,* although the latter two taxa appeared particularly resistant to *Micrurus* venom. Five species elicited no response in the coral snakes: *Adelphicos quadrivirgatus*, Boa constrictor, Drymobius margaritiferus, Leptotyphlops goudotii,* and *Tantilla schistosa**. Six species were not only rejected as prey but they also appeared to elicit strong escape responses in both species of *Micrurus*: *Coniophanes fissidens, C. piceivittis, Ficimia publia*, Rhadinaea decorata, Stenorrhina degenhardti**, and *Toluca lineata.* (* indicates that Roze reported records of these or closely related species in the diet of *M. diastema;* no specific records were reported for *M. limbatus.*)

We initially also offered *Conophis lineatus* to the coral snakes, but this was discontinued early in the study after a 42 cm *C. lineatus* devoured a 70 cm *M. diastema* and a 50 cm *M. limbatus.* No other taxa were observed to attack the coral snakes during our tests.

SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA; and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309, USA.

MICRURUS NIGROCINCTUS (Coral Snake). **REPRODUCTION.** Palo Verde National Park is a seasonal dry forest in northwestern Costa Rica (10°19'–10°24'N and 85°18'–85°25'W). One of us (MP) observed a pair of *M. nigrocinctus* copulating in the park (ca. 20 m above sea level on the lower slopes of a 210 m limestone hill). Copulation in this species under natural conditions has not been reported.

On 14 October 1995 at 1100 h, the intertwined tails of two *M. nigrocinctus* were discovered protruding from underneath a log. MP retrieved a Sony Hi-8 camcorder and returned with three other people about 10 min later. The snakes' tails had not moved and MP immediately started taking video. Approximately 3 min later, the log was lifted and the two snakes were completely exposed. When the log was first lifted, the tails were intertwined and the bodies were coiled with the male positioned slightly more on top. The snakes were both ca. 80–90 cm total length, and the male appeared slightly thinner than the female. The female was opaque in color and clearly was in a shed cycle, though her eyes were not noticeably opaque. The snakes were disturbed by the sunlight and/or presence of people, and soon after pulled apart and moved under a nearby log. The everted right hemipenis of the male was observed as the snakes ended the copulation.

A copy of the video tape (ca. 6 min duration) is on file at the Museum of Vertebrate Zoology.

Submitted by **MELISSA A. PANGER**, Department of Anthropology, 232 Kroeber Hall, University of California, Berkeley, California 94720, USA, and **HARRY W. GREENE**, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA.

OPHEODRYS AESTIVUS (Rough Green Snake). **SPIDER-WEB ENTRAPMENT.** On 8 October 1995 in the town of Elkton, St. John's Co., Florida, USA, we observed an adult *Opheodrys aestivus* (75 cm SVL) approximately 6 m up in a stand of laurel oaks (*Quercus laurifolia*). The snake was dead, bound and suspended in the web of a golden orb-weaving spider, *Nephila clavipes* (Araneidae). The spider, an adult female, was still present, but no interactions were observed. Neither animal was collected. It is unclear how the snake became entrapped in the spider web, but one possibility is that this was an act of predation. Spiders of this genus are known to prey on vertebrates (McKeown 1963. Australian Spiders, Angus and Robertson, Sydney, 287 pp.; Hill and Phillipps 1981. A Colour Guide to Hong Kong Animals. Government Printer, Hong Kong, 281 pp.). Without further evidence, however, we must conclude that this entrapment was an unusual and previously unreported cause of mortality in *O. aestivus*.

Submitted by **KEVIN C. ZIPPEL**, Department of Zoology, University of Florida, Gainesville, Florida 32611, USA, and **LYNN KIRKLAND**, St. Augustine Alligator Farm, St. Augustine, Florida 32085, USA.

PSEUDOBOA CORONATA (False Coral Snake). **DIET.** *Pseudoboa coronata* is known to eat small rodents (Cunha and Nascimento 1983. Bol. Mus. Para. Emílio Goeldi, nova ser. Zool. 122:1–42), as well as ground birds, small fishes, and lizards (Beebe 1946. Zoologica 31:11–52; Cunha and Nascimento 1978. Publ. Avul. Mus. Para. Emílio Goeldi 31:1–217; Duellman 1978. Misc. Publ. Univ. Kansas Mus. Nat. Hist. 65:1–352). *Pseudoboa nigra*, although considered mainly saurivorous (Vanzolini et al. 1980. Répteis das Caatingas, Acad. Bras. Ciências, 161 pp.), is the only species of the genus known to eat snakes (Cunha and Nascimento 1983, *op. cit.*). Here we report ophiophagy in *P. coronata*.

In December 1995, a female *P. coronata* (Museu Paraense Emílio Goeldi [MPEG] 19027, 568 mm SVL, 13.8 mm max. diam, 68 g preserved) from Ananindeua (1°22'S, 48°23'W), Pará, Brazil, was found alive with the posterior 8 cm of an adult *Mastigodryas boddaerti* (MPEG 19028, 757 mm SVL, 10.5 mm max. diam, 27 g preserved) protruding from its mouth. The *P. coronata* had been unable to completely swallow the much larger *M. boddaerti*; however, digestion of the anterior portion of the prey was well underway.

Ingestion of large prey presents a physical challenge to a snake and may lead to increased vulnerability to predators by complicating locomotion (Sazima and Martins 1990. Mem. Inst. Butantan 52[3]:73–79). However, if these potential problems can be overcome and the prey is not regurgitated, there is a huge energetic reward for the predator (Schoener 1971. Ann. Rev. Ecol. Syst. 2:369–404).

We thank João Batista da Silva, who collected the snake, and José Maria Cardoso da Silva for help with the manuscript.

Submitted by **ULISSES GALATTI** and **RUBENS NOBUO YUKI,** Departamento de Zoologia, Museu Paraense Emílio Goeldi, Caixa Postal 399, CEP 66040-170, Belém, Pará, Brazil. e-mail (UG): ulisses@museu-goeldi.br and (RY): yuki@museu-goeldi.br.

REGINA ALLENI (Striped Crayfish Snake). **ANTIPREDATOR BEHAVIOR.** On 21 November 1996 at 1330 h, a southern black racer (*Coluber constrictor priapus*) was observed consuming a *Regina alleni*. This occurred in a roadside ditch located on Avon Park Air Force Range, Highlands County, Florida, USA.

The *C. constrictor* (ca. 97 cm SVL) had grabbed the *R. alleni* (ca. 38 cm SVL) around the base of the skull. The lower one third of the *R. alleni* was tightly coiled around the vegetation in an apparent attempt to prevent being swallowed. The *C. constrictor*

followed short intervals of ingestion by quick jerks of its head, possibly to pull the *R. alleni* from the vegetation. The *C. constrictor* appeared more agitated during the second half of the event, when it began engulfing the *R. alleni* faster, jerking its head with more force, and vibrating its tail. The *C. constrictor* interrupted feeding for 13 min when it encountered the still-fastened coils of the *R. alleni*. Feeding resumed at 1425 h when the *R. alleni* released its grasp on the vegetation and became motionless. At 1440 h, the *C. constrictor* paused, with ca. 5 cm of the prey still visible, then retreated to a patch of saw palmetto.

The *C. constrictor* appeared to have difficulty consuming the *R. alleni* when the latter was coiled about vegetation. Guyer and Laska (1996. Herpetol. Rev. 27:203) reported a *Boa constrictor* that also coiled its body in such a way as to interfere with a predation attempt.

I thank Dick Franz for helpful suggestions, and Pat Walsh of the Avon Park Air Force Range Natural Resources Staff for providing access to the site. This research was funded by the Avon Park Air Force Range through Cooperative Agreement 1445-0009-1544, Research Work Order No. 169 of the Florida Cooperative Fish and Wildlife Research Unit.

Submitted by **CHRISTOPHER J. O'BRIEN**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611-7800, USA.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins 1997. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*. Fourth Edition. SSAR Herpetol. Circ. 25:1–40; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*. Herp. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: Joseph T. Collins (USA & Canadian records only), Museum of Natural History—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA; Jerry D. Johnson (México and Central America, including the Caribbean islands), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA; Hidetoshi Ota (all Old World records), Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; or Gustavo J. Scrocchi (South American records), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Submissions by e-mail are encouraged where possible**. Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Marques, O. A. V., and G. Puorto. 1996. Geographic Distribution. *Chironius laevicollis*. Herpetol. Rev. 27:212.

CAUDATA

AMBYSTOMA CINGULATUM (Flatwoods Salamander). USA: FLORIDA: Jefferson Co: State Road 59, 8.4 km N of jct. with U.S. Rt. 98, SE 1/4 Sec. 32, T2S, R3E. One live adult examined closely then released by D. B. Means as it was moving E to W at 2230 h on 31 October 1997. A second adult was found squashed 50 m S of first location at 2355 h on 29 November 1997 by D. B. Means. Verified by David Auth. UF 108837. First record for Jefferson County; partly rejects the hypothesis that the species is naturally absent from the Florida panhandle between the Suwannee River and Wakulla County because of biogeographical reasons (Palis 1997, Herpetol. Nat. Hist. 5:53–65). Almost all of the adult natural habitat of *A. cingulatum* in southern Jefferson County has been converted to dense slash pine plantations (Means and Palis 1995. Conserv. Biol. 10:426–437), but aerial photographs indicate that small cypress domelike wetlands—potential breeding habitat—are still common in the landscape. Palis's (ibid.) other hypothesis, sampling bias, is not rejected.

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute, 1313 North Duval Street, Tallahassee, Florida 32303, USA.

AMBYSTOMA MACULATUM (Spotted Salamander). USA: PENNSYLVANIA: Schulkyll Co: small runoff pond along Blue Mountain Railroad, adjacent to the Little Schulkyll River, ca. 1.6 km N of Hawk Mountain Road. 9–12 June 1996. C. Paul Rogers and Todd Bauman. Jacksonville State University Collection (JSUC A012–A024) Larvae verified by G. R. Cline. New county record; fills gap among neighboring counties. Specimens collected at Hawk Mountain Sanctuary fill in the gap between central Berks county specimens and the new county record.

Submitted by **C. PAUL ROGERS**, Department of Biology, Jacksonville State University, Jacksonville, Alabama 36265-1602, USA, and **TODD BAUMAN**, Hawk Mountain Sanctuary, Kempton, Pennsylvania 19759-9449, USA.

EURYCEA CIRRIGERA (Southern Two-lined Salamander). USA: TENNESSEE: Hardin Co: 2.4 km E Counce, Robinson Creek (Tennessee River drainage) at Tenn. Rt. 57 (35°02.929'N, 88°15.074'W). 27 March 1996. C. A. Taylor and M. H. Sabaj. Illinois Natural History Survey (INHS 12318). Verified by C. A. Phillips. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

Submitted by **JOHN E. PETZING** and **MARK H. SABAJ**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

EURYCEA CIRRIGERA (Southern Two-lined Salamander). USA: TENNESSEE: Moore Co: 10 km NE Lynchburg, Hurricane Creek at Raysville Road (35°20.789'N, 86°17.859'W). 15 March 1996. Jeanne Serb, Thomas Near, Patrick Ceas and Jean Porterfield. Illinois Natural History Survey (INHS 12257). Veri-

fied by Christopher A. Phillips. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

Submitted by **JEANNE M. SERB** and **JOHN E. PETZING**. Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

PLETHODON DORSALIS (Zigzag Salamander). USA: TENNESSEE: Hickman Co: 4 km NW Primm Springs, Tatum Creek at Tatum Creek Road (35°51.161'N, 87°16.903'W). 15 March 1996. Jeanne Serb, Thomas Near, Patrick Ceas and Jean Porterfield. Illinois Natural History Survey (INHS 12261). Verified by Christopher A. Phillips. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

ANURA

ADENOMERA cf. ***MARMORATA***. BRAZIL: RIO GRANDE DO SUL: Municipio São Francisco de Paula: Centro de Pesquisas e Conservação da PUCRS (Pró-Mata, 29°30'S, 50°10'W). 1000 m. 20 December 1996. Axel Kwet. Museu de Ciências da PUCRS (MCP 2421). Verified by Andreas Schlüter. First record for the genus for Rio Grande do Sul. Related to *Adenomera marmorata*, but with different calls in the more northerly populations of this species near São Paulo (Heyer et al. 1990, Arquivos de Zoologia São Paulo 31[4]:230–410). Southernmost record for the genus *Adenomera*. Common species in the disturbed *Araucaria* forest of the Pró-Mata Reserve.

Submitted by **AXEL KWET**, Zoologisches Institut der Universität Tübingen, Lehrstuhl für spezielle Zoologie, Auf der Morgenstelle 28, D-72076 Tübingen, Germany.

BUFO AMERICANUS AMERICANUS (Eastern American Toad). USA: MINNESOTA: Crow Wing Co: 22.5 km NE Brainerd. July 1949. R. C. Schroder. Verified by C. A. Phillips. Illinois Natural History Survey (INHS 4240). Confirms literature/sight record (Oldfield and Moriarty. 1994 Amphibians and Reptiles Native to Minnesota. University of Minnesota Press).

Submitted by **JOHN E. PETZING,** Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

BUFO SPECIOSUS (Texas Toad). USA: NEW MEXICO: Otero Co: 9.2 km (road) N of Texas border on New Mexico Rt. 506, N edge Sec. 3, T26S, R18E. 31 August 1991. William G. and Paula B. Degenhardt. University of New Mexico Museum of Southwestern Biology (MSB 60774). Verified by Charles W. Painter. First record for county and extends range ca. 50 km W of the Eddy County records plotted in Degenhardt et al. (1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **WILLIAM G. DEGENHARDT**, Museum of Southwestern Biology, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

ELEUTHERODACTYLUS MARNOCKII (Cliff Chirping Frog). USA: TEXAS: Tom Green Co: S Concho River, 8 km S Christoval, 756 m (31°08'17"N, 100°29'38"W). 31 May 1996. J. F. Husak and M. S. Husak. Angelo State Natural History Collection (ASNHC 12885). Verified by T. C. Maxwell. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JERRY F. HUSAK**, Department of Biology, Angelo State University, San Angelo, Texas 76909, USA.

GASTROPHRYNE ELEGANS (Elegant Narrowmouth Toad). MÉXICO: TAMAULIPAS: Rancho Los Colorados, 26 km NE Aldama, 5 m. 12 January 1992. James R. Dixon. TCWC 70392. Verified by Kathryn Vaughan. First state record and northward range extension of 240 airline km from 6 km NW Tihuatlan, Veracruz (UIMNH 3625). Found under a stone following moderate rainfall.

Submitted by **XOCHITL SAMPABLO-BRITO**, Universidad de Tamaulipas, Cuidad Victoria, Tamaulipas, México, and **JAMES R. DIXON**, 705 Inwood Drive, Bryan, Texas 77802, USA.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: TEXAS: Stonewall Co: 0.5 km N Texas Rt. 83 in Salt Fork of the Brazos River. 2 August 1997. Kenneth G. Ostrand, Warren C. Conway, Ricardo Jimenez, Jr., Randy R. Young. Museum of Texas Tech University (MTTU 11766). Verified by Ann M. Anderson. County record. One individual observed in riverside pool. Expands the range of this species (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). Previously reported distributions included counties surrounding Lubbock.

Submitted by **KENNETH G. OSTRAND**, **WARREN C. CONWAY**, **RICARDO JIMENEZ, JR.**, and **RANDY R. YOUNG**, Department of Range, Wildlife, and Fisheries Management, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79409-2125, USA.

HYLA AVIVOCA (Bird-Voiced Treefrog). USA: GEORGIA: Jasper Co: Charlie Elliott Wildlife Center, Margery Lake, 33°27'26"N, 83°43'54"W. 24 May 1997. John B. Jensen. UGAMNH 37052. Jones Co: Piedmont National Wildlife Refuge, Allison Lake, 33°07'07"N, 83°41'19"W. 9 July 1997. John B. Jensen. UGAMNH 37051. Bibb Co: cove on west side of Lake Wildwood, 32°51'59"N, 83°46'48"W. 14 June 1997. John B. Jensen. UGAMNH 37053.

Wharton (1978, Georgia Geol. Surv. Bull. 114:1–227) reported "a remarkable disjunct population" of *Hyla avivoca* within the Piedmont physiographic region of central Georgia. This population, thought to be isolated from populations of the Coastal Plain, is also depicted as disjunct in Conant and Collins (1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Records noted above document its occurrence in three continuous counties between previously known sites in the Piedmont and the upper Coastal Plain, and represent new county records (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Publ. 3:1–712). Further, these new records suggest a continuous range of this species along the Ocmulgee River drainage of central Georgia.

All specimens were verified by M. E. McGhee, and are deposited in the University of Georgia Museum of Natural History (UGAMNH).

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA; e-mail: forsyth_nongame@mail.dnr. state.ga.us.

HYLA MICROPS (Nova Friburgo Treefrog). BRAZIL: RIO GRANDE DO SUL: Municipio São Francisco de Paula: Centro de Pesquisas e Conservação da PUCRS (Pró-Mata, 29°30'S, 50°10'W). 1000 m. 26 January 1997. Axel Kwet. Museu de Ciências da PUCRS (MCP 2476–2480). Verified by Andreas Schlüter. First record for Rio Grande do Sul. Common species in forests and near-forest areas of the Pró-Mata Reserve.

Submitted by **AXEL KWET**, Zoologisches Institut der Universität Tübingen, Lehrstuhl für spezielle Zoologie, Auf der Morgenstelle 28, D-72076 Tübingen, Germany.

HYLA TRITAENIATA. BRAZIL: MATO GROSSO DO SUL: Sonora municipality: Rio Correntes along the left bank in a small fen located near low waterfalls and in front of a small sandy beach locally known as "Prainha," (17°36'S, 54°49'W). 2 November 1994. C. Strussmann. Coleção de Vertebrados do Instituto de Biociências da Universidade Federal de Mato Grosso (UFMT 2147–50). Verified by Marcelo Napole. First state record. Species was described by Bokermann (1965, Rev. Brasil. Biol. 25[3]:259) from São Vicente (Cuiabá municipality) and Rondonópolis, both in the state of Mato Grosso, and apparently has not been mentioned in the literature since the original description. Locality here reported extends known distribution ca. 130 km to the south.

Submitted by **CHRISTINE STRUSSMANN**, Rua Antonio Dorileo 508, Apartado 34, Residencial Coxiponês, COOPHEMA, 78085-600 Cuiabá, Mato Grosso, Brazil.

PHRYNOHYAS IMITATRIX (Rio Golden-eyed Treefrog). BRAZIL: RIO GRANDE DO SUL: Municipio São Francisco de Paula: Centro de Pesquisas e Conservação da PUCRS (Pró-Mata, 29°30'S, 50°10'W). 1000 m. 19 December 1996. Axel Kwet. Museu de Ciências da PUCRS (MCP 2422). Verified by Andreas Schlüter. First record for Rio Grande do Sul and second species of the genus *Phrynohyas* in the state. The female specimen was found after heavy rains on a road in the forest of Pró-Mata Reserve.

Submitted by **AXEL KWET**, Zoologisches Institut der Universität Tübingen, Lehrstuhl für spezielle Zoologie, Auf der Morgenstelle 28, D-72076 Tübingen, Germany.

PHYLLOMEDUSA TARSIUS (Brownbelly Leaf Frog). VENEZUELA: PORTUGUESA: Distrito Guanare: 23 km NW Guanare on road to Biscucuy (90°09'N; 69°53'W), 360 m. 18 November 1990 (2200 h). Allan L. Markezich and Donald C. Taphorn. Universidad Nacional Experimental de los Llanos Occidentales Ezequiel Zamora, Coleccion de Anfibios, Museo de Ciencias Naturales (MCNG 2527). Verified by William E. Duellman. First record from Portuguesa and the second documented specimen as well as the northernmost and highest elevational record from western Venezuela. It was collected ca. 220 km NNE of the first western Venezuelan record, which was from the state of Barinas (La Marca 1996, Herpetol. Rev. 27:149). Only one other specimen is known from Venezuela—in the state of Bolivar in the eastern region of the country (La Marca, *op. cit.*).

Submitted by **ALLAN L. MARKEZICH**, Department of Natural Sciences and Engineering, Black Hawk College, Moline, Illinois 61265-5899, USA.

PHYSALAEMUS AGUIRREI. BRAZIL: BAHIA: Caravelas (17°43'S, 39°15'W). 9 April 1997. Monique Van Sluys. Museu Nacional do Rio de Janeiro (Cat. No. 18916). Verified by José Perez Pombal Jr. Individuals were collected using pitfalls with drift fences set in Restinga vegetation. Known only from type locality (Atlantic Rainforest in Linhares, Espírito Santo; Duellman 1993, Univ. Kansas, Mus. Nat. Hist. Spec. Publ. 21:1–372). First record for state of Bahia; extends range ca. 600 km northward from type locality, and represents the northernmost record for the species.

Submitted by **MONIQUE VAN SLUYS**, Setor de Ecologia, DBAV, IB, Universidade do Estado do Rio de Janeiro, 20550-013, Rio de Janeiro, Rio de Janeiro, Brazil. e-mail: vansluys@uerj.br.

PHYSALAEMUS CROMBIEI. BRAZIL: BAHIA: Nova Viçosa (17°53'S, 39°22'W). 7 April 1997. Monique Van Sluys. Museu Nacional do Rio de Janeiro (Cat. Nos. 19035–19038). Verified by José Perez Pombal Jr. Individuals were collected using pitfalls with drift fences set in Atlantic Rainforest. Known only from type locality (Santa Tereza, Espírito Santo; Duellman 1993, Univ. Kansas, Mus. Nat. Hist. Spec. Publ. 21:1–372). First record for state of Bahia; extends range ca. 600 km northward from type locality, and represents the northernmost record for the species.

Submitted by **MONIQUE VAN SLUYS**, Setor de Ecologia, DBAV, IB, Universidade do Estado do Rio de Janeiro, 20550-013, Rio de Janeiro, Rio de Janeiro, Brazil; e-mail: vansluys@uerj.br.

RANA BLAIRI (Plains Leopard Frog). USA: TEXAS: KENT CO: jct. Texas Rt. 208 and the Double Mountain Fork of the Brazos River. 23 August 1997. Kenneth G. Ostrand, David J. Echels, Warren C. Conway, Jarrod DePew, Gregory D. Pleasant. Museum of Texas Tech University (MTTU 11765). Verified by Ann M. Anderson. County record. One individual observed in riverside pool. Expands range of species (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). Previously reported distributions included all surrounding counties except Lynn County to the west.

Submitted by **KENNETH G. OSTRAND, DAVID J. ECHELS, WARREN C. CONWAY, JARROD DEPEW**, and **GREGORY D. PLEASANT**, Department of Range, Wildlife, and Fisheries Management, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79409-2125, USA.

RANA FORRERI (Forrer's Grass Frog). MÉXICO: MÉXICO: Municipio de Ixtapan de la Sal: San Alejo (18°50'13"N, 99°43'30"W) 1650 m. 20 November 1994. R. Cruz. Colección Herpetológica del Instituto de Biología, Universidad Nacional Autónoma de México (IBH 11131). Chalma-Malinalco (18°54'52"N, 99°27'52"W) 1560 m. 13 May 1979. J. L. Camarillo (IBH 3244–47). Municipio de Tejupilco: 1–3 km al E de Bejucos (18°46'30"N, 100°25'30"W) 520 m. 25 June 1982. A. Ramirez y E. Ramos (IBH 3915). Verified by Fausto R. Méndez de la Cruz. First records for the state of México. (Camarillo and Smith 1992, Greater Cinncinatti Herpetol. Soc. Contr. Herpetol. [1]:39–41).

Submitted by **GUSTAVO CASAS-ANDREU**, Instituto de Biología, Universidad Nacional Autónoma de México, Apartado

Postal 70-153, 04510 México, Distrito Federal, México, and **GABRIEL BARRIOS QUIROZ** and **RICARDO CRUZ AVINA**, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario 100, 50000 Toluca, Estado de México, México.

RANA SPHENOCEPHALA UTRICULARIUS (Southern Leopard Frog). USA: TEXAS: Rockwall Co: Rt. 205, ca. 2 mi S of Rockwall at 0930 h during heavy rain. AOR. 19 May 1997. C. J. Franklin. University of Texas at Arlington Collection of Vertebrates (UTA A-51506). Verified by R. L. Gutberlet. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp).

Submitted by **CARL J. FRANKLIN**, Department of Herpetology, Dallas Zoo, 650 South R. L. Thorton Freeway (I-35), Dallas, Texas 75203, USA.

SPEA BOMBIFRONS (Plains Spadefoot). USA: COLORADO: Saguache Co: wetlands on S side of -E- Road, 3 km E 63 Road. 23 June 1997. M. B. Wunder. UCM 58813–14; 2 km N Weisman Lake. 27 July 1997. M. B. Wunder. UCM 58806. All verified by Hobart M. Smith. First county records (Livo et al. 1997, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. 1997 Interim Summary. Publ. Colorado Herpetol. Soc.).

Submitted by **MICHAEL B. WUNDER**, **JEREMY L. SIEMERS**, and **ANNE E. OCHS**, Colorado Natural Heritage Program, Colorado State University, Fort Collins, Colorado 80523, USA.

TESTUDINES

APALONE SPINIFERA ASPERA (Gulf Coast Spiny Softshell). USA: GEORGIA: Lanier Co: Alapaha River, ca. 2.5 km downstream from Georgia Rt. 37 bridge, 31°01'16"N, 83°02'02"W. 5 June 1997. John B. Jensen and William Whitesell. UGAMNH 36540. Verified by M. Elizabeth McGhee. Juvenile male captured in a baited hoop-trap set overnight. New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712), and although unvouchered records exist for Berrien and Irwin counties, Georgia (Knepton 1956, J. Tennessee Acad. Sci. 31[4]:322–324), this also represents the first confirmed record for the entire Suwannee River drainage (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

CYCLEMYS DENTATA (Asian Leaf Turtle). INDONESIA: KALIMANTAN BARAT: Kalimantan Timur: Upper reach of Belayan River at Sungai Durian, ca. 50 km upstream from Tabang. 15 August 1996. I. Gyurján. Hungarian Natural History Museum (HNHM 97.1.1). Verified by U. Fritz. First record for East Kalimantan Province, ca. 750 air km NE of the only documented locality in Indonesian Borneo (Iverson 1992, A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana, 363 pp.).

Submitted by **BALÁZS FARKAS** and **ISTVÁN GYURJÁN**, Department of Zoology, Hungarian Natural History Museum, Pf. 137, H-1431 Budapest, Hungary.

ERETMOCHELYS IMBRICATA (Hawksbill). USA: FLORIDA: Monroe Co: Key West National Wildlife Refuge, Marquesas Keys, 24°34'1"N, 82°10'0"W, ca. 35 km W Key West. UF 105430–31. Verified by Anne Meylan. Nest found on 22 December 1995 was excavated on 30 March 1996 and contained 146 eggs (6 dead hatchlings, 140 unhatched eggs). Unhatched eggs with well-developed embryos collected for species confirmation. First nesting record for Marquesas Keys (Anne Meylan, pers. comm).

Submitted by **THOMAS J. WILMERS**, National Key Deer Refuge, P.O. Box 430510, Big Pine Key, Florida 33043, USA, and **ELAINE M. WILMERS**, 30246 Watson Boulevard, Big Pine Key, Florida 33043, USA.

KINOSTERNON BAURII (Striped Mud Turtle). USA: GEORGIA: Glynn Co: Jekyll Island, Georgia Rt. 50 (Beachview Drive), 0.5 mi S from Georgia Rt. 50/US Rt. 520 jct. (31°02'78"N, 81°24'51.2"W). 12 May 1997. Michael Frick. Savannah Ogeechee Canal Museum and Nature Center (SOCM 0344). Verified by Robert A. Moulis. New county and island record (Williamson and Moulis 1993, Savannah Sci. Mus. Publ. 3:1–712; R. A. Moulis, unpubl. data). CCL= 1.9 cm. CCW= 1.5 cm. Turtle was found dead on road apparently emerging from adjacent fresh water slough. Caruncle or egg tooth present and still showing an unhealed plastron from yolk sac absorption.

Submitted by **MICHAEL G. FRICK**, Caretta Research Project, Savannah Science Museum, 4405 Paulsen Street, Savannah, Georgia 31405, USA.

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow Mud Turtle). USA: COLORADO: Bent Co: Purgatoire River State Wildlife Area, SW 1/4 of NW 1/4 Sec. 27, T23S, R52W. 21 June 1995. Michelle D. Keefer and Steven D. Keefer. UCM Ancillary Herpetological Photographic Collection 134–136. Verified by Hobart Smith, David Chiszar, Geoffrey Hammerson, and Lauren Livo. First county record (Livo et al. 1997, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records: 1997 Interim Summary. Publ. Colorado Herpetol. Soc.).

Submitted by **STEVEN D. KEEFER** and **CHARLES W. LOEFFLER**, Colorado Department of Natural Resources, Division of Wildlife, 6060 Broadway, Denver, Colorado 80216, USA.

NOTOCHELYS PLATYNOTA (Malayan Flatshell Turtle). INDONESIA: KALIMANTAN BARAT: Kalimantan Timur: Upper reach of Belayan River at Sungai Durian, ca. 50 km upstream from Tabang. 15 August 1996. I. Gyurján. Hungarian Natural History Museum (HNHM 97.2.1); slides of another specimen also deposited in HNHM. Verified by J. R. Buskirk. Extends range by ca. 400 air km SW and 325 air km E of nearest documented localities in Indonesian Borneo, and is possibly the first record for East Kalimantan Province (Iverson 1992, A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana, 363 pp.).

Submitted by **BALÁZS FARKAS** and **ISTVÁN GYURJÁN**, Department of Zoology, Hungarian Natural History Museum, Pf. 137, H-1431 Budapest, Hungary.

PSEUDEMYS CONCINNA SUWANNIENSIS (Suwannee River Cooter). USA: GEORGIA: Lowndes Co: Withlacoochee River near Knights Ferry Landing, 30°42'42"N, 83°27'17"W. 13 June 1997. John B. Jensen and Robert Moulis. UGAMNH 36539. Verified by Dale R. Jackson. Adult captured in a baited hoop-trap overnight. First state record for this subspecies. (Williamson and

Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712). More than 20 individuals of various size classes were observed basking on logs and rocks in the Withlacoochee River, and a similar number were also observed in the Alapaha River (5 June 1997) in both Lanier and Echols counties. Previously this species was unknown from the Georgia portion of the Suwannee River drainage (of which the Withlacoochee and Alapaha rivers are a part) as well as from its more northerly reaches within Florida (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

LACERTILIA

CNEMIDOPHORUS UNIPARENS (Desert Grassland Whiptail). USA: NEW MEXICO: Cibola Co: 49 km S and 1 km W Laguna, S Sec. 8, T4N, R5W. 29 July 1991. William G. and Paula B. Degenhardt. University of New Mexico Museum of Southwestern Biology (MSB 52807). Verified by James N. Stuart. New record for county and another record of sympatry with *C. velox*. Location is illustrated in Degenhardt et al. (1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.) as Habitat Photo Figure 9.

Submitted by **WILLIAM G. DEGENHARDT**, Museum of Southwestern Biology, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

CYCLURA CYCLURA FIGGINSI (Exuma Island Ground Iguana). BAHAMAS: Exuma Island Chain: Leaf Cay. 0.5 km NE Norman's Pond Cay, 23°47'19"N, 76°07'90"W. 28 March 1997. Chuck Knapp. Two specimens photographed (UF 107144, unsexed adult, UF 107145, adult male). Verified by David L. Auth. First record for Leaf Cay; nearest recorded population inhabits North Adderly Cay, 0.4 km north of Leaf Cay. Augments documentation by Schwartz and Henderson (1988, West Indian Amphibians and Reptiles: A Checklist. Publ. Milwaukee Pub. Mus., Milwaukee, Wisconsin. 264 pp.)

Submitted by **CHUCK KNAPP**, Department of Conservation, John G. Shedd Aquarium, Chicago, Illinois 60605, USA, and **SANDRA BUCKNER**, P.O. Box N8893, Nassau, The Bahamas.

GECKONIA CHAZALIAE (Helmethead Gecko). A correction. MAURITANIA. Schleich et al. (1996, Amphibians and Reptiles of North Africa. Koeltz Scientific Publ. ii + 630 pp: map page 235) show *G. chazaliae* as occurring continuously throughout the coastal area of Mauritania. This continuous distribution differs from previous interpretations which recognize *G. chazaliae* present only at Cape Blanc (21°07'97/100N, 16°57'45/100W), the type locality of this species, and then appearing further south in Senegal. This distributional hiatus is approximately 500 km wide. Our recent surveys in this gap have not found any specimens of this species nor do any exist in any European museums.

Submitted by **IVAN INEICH**, Muséum national d'Histoire naturelle, Laboratoire de Zoologie (Reptiles & Amphibians), 25 rue Cuvier, F-75005 Paris, France (e-mail: ineich@cimrs1.mnhn.fr), **AMADOU TIDIANE DIA** and **BOCAR ALPHA LY**, Centre National d'Elevage et de Recherches Vétérinaires, BP 167, Nouakchott, Islamic Republic of Mauritania, and **FRANCOIS COLAS**, CIRAD-EMVT, Département d'Elevage et de Médecine Vétérinaire du CIRAD, BP 5035, F-34032 Montpellier Cedex 1, France.

HEMIDACTYLUS FRENATUS (House Gecko). MÉXICO: MÉXICO: Municipio de Tejupilco: Bejucos (18°46'30"N, 100°25'30"W), 600 m. 1 May 1997. R. Cruz and G. Barrios. Colección Herpetológica del Instituto de Biología, Universidad Nacional Autónoma de México (IBH 11262). Verified by Adrian Nieto Montes de Oca. First state record (Camarillo and Smith 1992, Greater Cincinnati Herpetol. Soc. Contr. Herp. 1:39–41).

Submitted by **GUSTAVO CASAS-ANDREU**, Instituto de Biología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, 04510 México, Distrito Federal, México, **GABRIEL BARRIOS QUIROZ** and **RICARDO CRUZ AVINA**, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario 100, 50000, Toluca, Estado de México, México.

LAEMANCTUS SERRATUS SERRATUS (Serrated Casquehead Iguana). MÉXICO: PUEBLA: municipality of Heuhuetla: Sierra Norte near Huehuetla (20°6'N, 97°37'W), 14 km NW Cuetzalan del Progreso, 460 m. 10 January 1996. Enrique Martínez Romero. Captured in disturbed tropical rain forest (INEGI 1987, Síntesis Geográfica, Nomenclator y Anexo Cartográfico del Estado de Peubla, Carta de Vegetación). Laboratorio de Herpetología, Escuela de Biología, Universidad Autónoma de Puebla (EBUAP-481). Verified by Adrián Nieto Montes de Oca. First record for the state and extends range 127 km (airline) SW from the closest known locality in Veracruz (Tamiahua) (McCoy 1968, Copeia 1968:665–678).

Submitted by **LUIS CANSECO-MARQUEZ** and **QUADALUPE GUTIERREZ-MAYEN**, Laboratoria de Herpetología, Escuela de Biología, Universidad Autónoma de Puebla, Ciudad Universitaria, Edificio 76, Blvd. Valsequillo y Avenida San Claudio, Col. San Manuel, CP. 72570, Puebla, Puebla, México.

NEUSTICURUS ECPLEOPUS. BRAZIL: PARA: Municipio de Paragominas: Fazenda Cauaxi (03°45'S, 48°25'W). 21–30 June 1997. Juliana M. da Silveira, Celso B. Miranda and Claudia Azevedo-Ramos. Museu Paraense Emilio Goeldi (MPEG 17940–44). Verified by Rubens Nobuo Yuki. Specimens collected in small streams ("igarapes") in primary forest. Extends the range ca. 380 km N from previous known locality in southeastern Para (Avila Pires 1995, Zool. Verch. 299:427–436) and represents the the easternmost range limit in Amazonia.

Submitted by **JULIANA M. DA SILVEIRA, CELSO B. MIRANDA**, and **CLAUDIA AZEVEDO-RAMOS**, DPE/Centro de Filosofia e Ciencias Humanas, Universidade Federal do Para, 66070-100 Belem, Para, Brazil. e-mail: claudia@ufpa.br.

SAUROMALUS OBESUS OBESUS (Western Chuckwalla). USA: NEVADA: Nye Co: ca. 100 m S of unpaved road (unmarked), 3 km off Rt. 95, 1.2 km SE of the Esmeralda County line (37°25'30.7"N; 117°08'09.5"W; 1451 m). 6 September 1997. R. E. Espinoza and C. A. Carreño. University of Nevada, Reno Vertebrate Museum, Herpetological Collection (UNR 5125). Verified by Bradford D. Hollingsworth. Represents the northernmost known locality in Nevada and extends the range ca. 30 km N (airline) from the closest reported locality near Bonnie Claire Flat in Esmeralda County (Ustach 1997, Herpetol. Rev. 28:158). Chuckwallas also were collected on isolated rock outcrops at two sites between the new and previously reported northern records: (UNR 5124) ca. 1 km off the N side of Rt. 267, ca. 10 km W of Scotty's Junction (37°09'30"N, 117°10'40"W, ca. 1200 m), and (UNR 5123) at Stonewall Pass, 6.6 km S of the Esmeralda County line on Rt. 95 (37°23'09"N, 117°08'29"W, 1512 m). These records

partially fill the gap between the Bonnie Claire Flat locality and the new northernmost record. In each case, these chuckwallas were found at elevations above those typically recorded for the species. This is especially noteworthy given their high latitudinal distribution.

SCELOPORUS ARENICOLUS (Dunes Sagebrush Lizard). USA: TEXAS: GAINES Co: shinnery dunes, ca. 0.1 air mi N jct Andrews/Gaines County line with New Mexico border, 32°31.435'N, 103°03.860'W. TAMU 77834. (male, 58 mm SVL, 60 mm tail [regenerated]); ca. 12 air mi S and 4.55 air mi E Hobbs, New Mexico, 32°31.435'N, 103°03.860'W. TAMU 77835 (male, 63 mm SVL, 47 mm tail [regenerated]). Both specimens 21 June 1997 by Charles W. Painter and Don Sias. Verified by A. M. Snyder. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game & Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **DON S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

SCELOPORUS CHANEYI (Chaney's Spiny Lizard). MÉXICO: TAMAULIPAS: Prov. Miquihuana: 12 km on road from La Pena to Valle Hermoso, 2550 m, in oak forest. 13 March 1996. TCWC 77268 (female); Joya Pelone, 21 km on road from La Pena to Villa Hermoso, 2880 m, in pine forest. 9 April 1996. TCWC 77269 (male), TCWC 77270 (female); El Aserradero, 15 km on road from La Pena to Villa Hermoso, 2640 m, in pine forest. 13 March 1996. TCWC 77271 (female). All specimens collected by Xochitl Sampablo-Brito and verified by Ernest Liner. Range extension of ±24 km S of summit of Sierra de la Gloria (CAS 165250–252), near the Nuevo Leon/Tamaulipas state line.

Submitted by **XOCHITL SAMPABLO-BRITO**, Universidad de Tamaulipas, Cuidad Victoria, Tamaulipas, Mexico, and **JAMES R. DIXON**, 705 Inwood Drive, Bryan, Texas 77802, USA.

TARENTOLA MAURITANICA (Common Wall Gecko). USA: CALIFORNIA: SAN DIEGO Co: 1.5 km S El Cajon city limits in a private residential community (32°46'15"N, 116°56'02" W), 200 m. 8 September 1997. Mike Sloop. San Diego Natural History Museum (SDSNH 68675). Verified by L. L. Grismer. An adult female 56 mm SVL (5.5 g) with ovarian eggs in right ovary. Several individuals were detected by the property owners in March 1996, one month after moving to the neighborhood. On the evening of 23 September 1997, I counted 10 individuals (7 adults, 3 hatchlings). Adults were extremely wary and observed near lights at the top of stucco walls and rafters on two buildings. Geckos were found on residential buildings 0.2 km from the core area, and populations >20 individuals have been observed. A resident said that a local pet shop sold this species and other exotic reptiles. It is unclear when the introduction occurred. The colony has survived at least two successive winters (1995–1996). This lizard is expected to expand its range from this localized site in San Diego area. Previously introduced in New Jersey via cork bark shipments from the Mediterranean region, but attempts to colonize were unsuccessful (Conant 1945, Copeia 1945:233). New state record and first record of a breeding population in the United States.

Submitted by **CLARK R. MAHRDT**, Herpetology Department, San Diego Natural History Museum, P.O. Box 1390, San Diego, California 92112, USA.

VANZOSAURA RUBRICAUDA. ARGENTINA: LA RIOJA: Department Chilecito: Chilecito (29°10'S, 67°30'W). July 1990. Guillermo Gnida. Herpetological collection of the Museo Argentino de Ciencias Naturales Bernardino Rivadavia, Buenos Aires, Argentina (MACN 33499); Department Capital: Dique Los Sauces, 22 km W La Rioja (29°25'S, 66°51'W). 7 October 1965. Emilio Maury. MACN 25153. All verified by Ricardo A. Martori. Extends range ca. 250 km air line NW from previous and vouchered citation in La Rioja province (Gallardo 1951, Com. Inst. Nac. Invest. Cs. Nat. Cs. Zool. Tomo II[1]:1–8).

Submitted by **LUCIANO JAVIER AVILA**, Centro Regional de Investigaciones La Rioja (CRILAR), Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Anillaco, La Rioja, Argentina.

XENOSAURUS NEWMANORUM (Xenosauro de Newman, Newman's Knob-scaled Lizard). MÉXICO: VERACRUZ: La Selva, 7.2 km E Huayacocotla (20°34'07"N, 98°30'17"W), 2000 m. 29 May 1991. Jose L. Camarillo R. Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autónoma de México (ENEPI 3884). Verified by Jonathan A. Campbell. Found on the ground in pine forest. First record for Veracruz (Smith and Smith 1976, Synopsis of the Herpetofauna of Mexico, Vol. 3. John Johnson, North Bennington, Vermont), and extends the range 103 km SE from type locality in Xilitla region, San Luis Potosí (King and Thompson 1968, Bull. Florida St. Mus. 12:93–123.

Submitted by **JOSE L. CAMARILLO R.**, Laboratorio de Herpetología, CYMA UIICSE, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autónoma de México, A.P. 314, Tlalnepantla, México.

SERPENTES

ARIZONA ELEGANS (Eastern Glossy Snake). USA: NEW MEXICO: GUADALUPE Co: 27.2 km SE of Santa Rosa, DOR. 26 September 1965. P. B. and W. G. Degenhardt. University of New Mexico Museum of Southwestern Biology (MSB 13821). Verified by Don S. Sias. First record for county (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **WILLIAM G. DEGENHARDT** and **JAMES N. STUART**, Museum of Southwestern Biology, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

CHERSODROMUS LIEBMANNI (Leibmann's Earth Runner). MÉXICO: OAXACA: Municipality of Totontepec Villa de Morelos, Totontepec (17°15'N, 96°01'W), 1840 m. 26 March 1992. José Luis Camarillo Rangel. Colección Herpetología, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autónoma de México (ENEPI 04593). Verified by Aurelio

Ramírez Bautista. Second record for the state and extends range 99 km SE (straight line) from Peña Verde, Oaxaca (Canseco and Flores 1995, Herpetol. Rev. 26:109).

Submitted by **MARIO MANCILLA-MORENO**, Laboratorio de Herpetología, Departamento de Zoología, Instituto de Biología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, C.U. 04510, México 20, Distrito Federal, México, and **JOSE LUIS CAMARILLO RANGEL**, Laboratorio y Colección de Herpetología, CyMA, Escuela Nacional de Estudios Profesional Iztacala, Universidad Nacional Autónoma de México, Apartado Postal 314, Tlalnepantla, Estado de México, México.

CHIRONIUS FLAVOLINEATUS (Cobra-cipó, Boettger's Sipo). BRAZIL: AMAZONAS: HUMAITÁ: Escola Agrotécnica Humaitá (7°31'S, 63°02'W). 9 November 1991. Guarino R. Colli. Colecão Herpetológica da Universidade de Brasília (CHUNB 00217–218). AMAPÁ: FERREIRA GOMES: Fazenda Teimoso (1°02'06"N, 51°10'02"). 17 April 1997. Guarino R. Colli and Ayrton K. Péres Jr. CHUNB 00219. All verified by Nelson Jorge da Silva Jr. First records for the states of Amapá and Amazonas; both sites in Amazonian Savanna habitats; extends range ca. 250 km NW from previous northern limit of distribution [Ilha de Marajó; Dixon et al. 1993, Revision of the Neotropical Snake Genus *Chironius* Fitzinger (Serpentes, Colubridae). Monographie XIII, Museo Regionale di Scienze Naturali, Torino. 279 pp.] and ca. 800 km N of western limit of distribution (central Bolivia, *ibid.*).

Submitted by **GUARINO R. COLLI** and **AYRTON K. PÉRES JR.**, Departamento de Zoologia, Universidade Brasília, 70910-900, Brasília, Distrito Federal, Brazil; e-mail (GRC): grcolli@guarany.cpd.unb.br.

CLONOPHIS KIRTLANDII (Kirtland's Snake). USA: KENTUCKY: GRAVES CO: on Bellville Road, 0.1 km W jct. with Kentucky Rt. 97. 14 July 1997. Collected by Scott Shupe. Department of Biology, Murray State University (MSU 1451). Verified by Ed Zimmerer. This locality is ca. 150 km SW of the closest known site and is in the Terrepene Creek drainage, a tributary of the Obion River system which drains most of west Tennessee to the Mississippi River.

Submitted by **SCOTT SHUPE**, Woods & Wetlands Wildlife Center, P.O. Box 469, Cadiz, Kentucky 42211, USA, and **ED ZIMMERER**, Department of Biological Sciences, Murray State University, Murray, Kentucky 42071, USA.

DASYPELTIS ATRA (African Egg-eating Snake). TANZANIA: RUKWA REGION: Mbizi Forest Reserve, 7°53'36"S, 31°40'32"E, 2250 m. January 1997. Mogens Andersen. Zoological Museum, University of Copenhagen (ZMUC R6122). Verified by Jens Bødtker Rasmussen (following Broadley and Howell 1991, Syntarsus 1:1–70). Previously only known in Tanzania from the northern part of the country; Bukoba and Mt. Klimanjaro (Broadley and Howell 1991, *op. cit.*). This new locality is situated 550 km (airline) from the previous southernmost locality, Mt. Kabobo on the NW coast of Lake Tanganyika in The Democratic Republic of Congo (Laurent 1956, Ann. Mus. Roy. Congo Belge, Sér. 8 , Sci. Zool., Vol. 48).

Submitted by **PETER GRAVLUND, ANDERS BERGGREEN,** and **MOGENS ANDERSEN**, The Zoological Museum, 1 Department, Herpetological Section, University of Copenhagen, Universitetsparken 15, DK-2100, Copenhagen, Denmark.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: WISCONSIN: ASHLAND CO: Rt. 2 km N of Prentice Park, Sec. 6, T47N, R4W. 9 September 1997. Seth Ames. Verified by Robert W. Henderson. MPM 30244. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Mus., Milwaukee, Wisconsin. 87 pp.). Extends range ca. 45 km NE of nearest records mapped by Vogt (1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee, Wisconsin. 205 pp.), and represents a departure from the bulk of records in NW Wisconsin, which fall within the Omega, Vilas soil region, characterized by sand barrens of jack pine and scrub oak (Hole 1980, Soil Guide for Wisconsin Landlookers. Publ. Geol. Nat. Hist. Surv., Univ. Wisconsin-Ext., Madison. 66 pp.). This occurrence was from a sandy lacustrine soil along Lake Superior, rather than within the red clay soils of the surrounding landscape.

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA, and **SETH AMES**, Northland College, Ashland, Wisconsin 54806, USA.

HYPSIGLENA TORQUATA DESERTICOLA (Desert Night Snake) USA: IDAHO: NEZ PERCE CO: Salmon River, UTM Zone 11. 519300E, 5089605N (m)(NAD27). 16 June 1995. Robin L. Llewellyn. Idaho Museum of Natural History (IMNH 1482). Verified by Charles R. Peterson. Found underneath a piece of driftwood along the Salmon River beach on Craig Mountain. In July 1996, two more snakes were located along the Salmon River, one underneath a piece of driftwood and the other caught in a funnel trap. New county record (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow. 332 pp.).

Submitted by **ROBIN L. LLEWELLYN**, Department of Biological Sciences, Idaho State University, Campus Box 8007, Pocatello, Idaho 83209, USA.

LAMPROPELTIS CALLIGASTER (Prairie Kingsnake). USA: TEXAS: ROCKWALL CO: Rt. 205. ca. 1.5 mi S Rockwall. DOR. 19 May 1997. C. J. Franklin. University of Texas at Arlington Collection of Vertebrates (UTA R-42502). Verified by C. L. Stewart. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp).

Submitted by **CARL J. FRANKLIN**, Department of Herpetology, Dallas Zoo, 650 South R. L. Thorton Freeway (I-35), Dallas, Texas 75203, USA.

LAMPROPELTIS GETULA CALIFORNIAE (California Kingsnake). USA: NEW MEXICO: SAN JUAN CO: San Juan River, ca. 7.6 km upstream (S) of confluence with Mancos River, 36°55'34.7"N, 108°57'26.3"W. 17 August 1997. Stephen R. Davenport. University of New Mexico Museum of Southwestern Biology (MSB 60810). Verified by W. G. Degenhardt. Found ca. 30 m from river in Cottonwood-Russian Olive grove at 2030 h. First record of this subspecies in New Mexico (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.). Extends range S from adjacent Montezuma County, Colorado, in San Juan River basin (Hammerson et al. 1991, Herpetol. Rev. 22:67).

Submitted by **STEPHEN R. DAVENPORT, JAMES N. STUART**, and **DONALD S. SIAS**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131-1091, USA.

LAMPROPELTIS TRIANGULUM CELAENOPS (New Mexico Milk Snake). USA: NEW MEXICO: GUADALUPE CO: U.S. Rt. 285 at S edge of Vaughn city limits (male, 420 mm SVL, 70 mm tail) KU Color Slide 11249; U.S. Rt. 285, ca. 2.5 mi (by road) S Vaughn (male, 330 mm SVL, 55 mm tail) KU Color Slide 11250. Both specimens collected 12 June 1997 by Brian Hubbs. Verified by J. E. Simmons. New county record (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **BRIAN HUBBS**, Box 802, Oakhurst, California 93644, USA.

LAMPROPELTIS TRIANGULUM TRIANGULUM (Eastern Milk Snake). USA: ILLINOIS: OGLE CO: 5 km W Oregon (SW 1/4 Sec. 4, T23N, R10E). 9 September 1997. Gaylen W. Parker. HDW-NIU 1667–1668. Verified by Richard King. New county record; range extension of 50 km between Winnebago and Dekalb County records (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298).

Submitted by **HARLAN D. WALLEY, ALEJANDRO QUERAL-REGIL,** and **TONYA BITTNER**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

MASTICOPHIS MENTOVARIUS MENTOVARIUS (Neotropical Whipsnake). MÉXICO: TABASCO: 18 km E Frontera. 7 September 1976. Diderot F. Gicca. UF 42337. Verified by F. Wayne King. First record for the state, bridging a coastal gap of over 500 km between records for southern Veracruz and central Campeche (Johnson 1982, Cat. Am. Amph. Rept. 295:1–4).

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA; **DAVID CHISZAR, HOBART M. SMITH** and **FRANK VAN BREUKELEN**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

NERODIA TAXISPILOTA (Brown Water Snake). USA: NORTH CAROLINA: NASH CO: 12.8 km N Rocky Mount, Swift Creek at U.S. Rt. 301 (36°04.687'N, 77°44.917'W). 25 June 1996. Jeanne Serb, Thomas Near, Mark Sabaj and Jonathan Armbruster. Illinois Natural History Survey (INHS 12638). Verified by Christopher A. Phillips. New county record (Palmer and Braswell 1995, Reptiles of North Carolina. Univ. North Carolina Press, Raleigh. xiii + 412 pp.).

Submitted by **JEANNE M. SERB** and **JOHN E. PETZING**, Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

PHILODRYAS OLFERSII (Lichtenstein's Green Racer). ARGENTINA: SANTA FE PROVINCE: La Capital Department: bank of Clucellas Island, Santa Fe stream (31°39'S, 60°42'W). 25 September 1997. Ambrosio Regner. Instituto Nacional de Limnología, Santa Fe (INALI 176, adult female). Verified by Alejandro R. Giraudo. First province record and the southwesternmost known population. Species previously known from Chaco, Corrientes, Entre Ríos, Formosa, Jujuy, Misiones, and Salta provinces in Argentina (Williams and Francini 1991, Boll. Mus. Reg. Sci. Nat. Torino 9[1]:75; Cei 1993, Mus. Reg. Sci. Nat. Torino Monogr. 14:637–638). The specimen was captured on a tree in the subtropical gallery forest in the alluvial valley of the Parana River.

Submitted by **ROQUE O. QUAINI**, Subsecretaría de Medio Ambiente y Ecología, Patricio Cullen 6161, 3000 Santa Fe, Argentina, and **VANESA ARZAMENDIA**, Instituto Nacional de Limnología (CONICET), José Macia 1933, 3016 Santo Tomé, Santa Fe, Argentina.

PHILODRYAS VIRIDISSIMUS (Common Green Racer). BRAZIL: BAHIA: Porto Seguro, Fazenda Vera Cruz (16°20'S, 39°10'W, 90 m). 14 November 1994. R. P. Silva. Instituto Butantan (IB 57195). Verified by Hebert Ferrarezzi. The species was known from the Amazonian forest of northern South America; its occurence in the Atlantic forest of eastern South America was uncertain (Thomas 1976, unpubl. Doctoral Dissertation, Texas A&M University, College Station). First record from Atlantic forest; extends distribution eastward.

Submitted by **OTAVIO A. V. MARQUES** and **FRANCISCO L. FRANCO**, Laboratorio de Herpetologia, Instituto Butantan, Avenida Vital Brasil, 1500, CEP 05503-900, São Paulo, São Paulo, Brazil.

PSEUDABLABES AGASSIZII. BRAZIL: MINAS GERAIS: Serra do Cipó (19°20'S, 43°44'W), ca. 1200 m, near Km 108 of MG-010 Road. 31 January 1997. Mara Cíntia Kiefer. Museu de História Natural da Universidade Estadual de Campinas (ZUEC 2075, female 256 mm SVL, 73 mm TL, 9.0 g body mass). Verified by Paulo R. Manzani and Ivan Sazima. Found while moving on the ground at 1200 h. Distribution known for southern and southwestern Brazil, northeastern Argentina, and Uruguay (Peters and Orejas-Miranda 1970, U.S. Natl. Mus. Bull. 297:252). First documented record for Minas Gerais; extends range of species eastward into southeastern Brazil.

Submitted by **MARA CÍNTIA KIEFER**, Museu de História Natural, Instituto de Biologia, Universidade Estadual de Campinas, Caixa Postal 6109, 13081-970 Campinas, São Paulo, Brazil.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). MÉXICO: DISTRITO FEDERAL: Delegación Alvaro Obregón, San Angel (99°12'N, 19°18'W). 13 June 1995. Zeferino Uribe. Colección Nacional de Anfibios y Reptiles (CONAR), Instituto de Biología, Universidad Nacional Autónoma de México (IBH 11281). Verified by Fernando Mendoza Quijano. First record for the district. Specimen was found in crop soil in a garden. Closest state where species was previously known is Morelos (Dixon and Hendricks 1979, Zoologische Verhandelingen 173:1–39).

Submitted by **MARIO MANCILLA-MORENO** and **AURELIO RAMIREZ-BAUTISTA**, Laboratorio de Herpetología, Departamento de Zoología, Instituto de Biología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, C.U. 04510, México 20, Distrito Federal, México.

SALVADORA GRAHAMIAE (Mountain Patchnose Snake). USA: NEW MEXICO: TORRANCE CO: DOR, U.S. Rt. 60, 17.7 km E jct. New Mexico Rt. 47, ca. 14.5 km SW Mountainair. 9 October 1997. Bruce L. Christman and Sandra L. Kilpatrick. University of New Mexico Museum of Southwestern Biology (MSB 60991). Verified by Donald S. Sias. VALENCIA CO: Lovelace Ranch, W of Los Lunas [ranch headquarters are ca. 32 km W and 13 km S Los Lunas, Sec. 31, T6N, R2W; precise locality not specified in original data]. 17 June 1967. Mike Williamson. MSB 18037. Verified by William G. Degenhardt. Both specimens represent new county records (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87205, USA, **SANDRA L. KILPATRICK**, 857 Sommerset Drive, Charleston, West Virginia 25302, USA,

CHARLES W. PAINTER, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

STORERIA DEKAYI (Brown Snake). USA: WISCONSIN: MARQUETTE Co: 5.6 km W Westfield and just NNW Lawrence Lake dam (35°53.03'N, 89°32.86'W). October 1996. R. Doerscheln. Verified by C. A. Phillips. Illinois Natural History Survey (INHS 12812). New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee, Wisconsin. 87 pp.).

Submitted by **JOHN E. PETZING** and **MARK H. SABAJ**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA, and **RONALD DOERSCHELN**, Westfield, Wisconsin, USA.

TANTILLA HOBARTSMITHI (Southwestern Blackhead Snake). USA: UTAH: CARBON Co: Rock Creek Ranch, Desolation Canyon, about 0.8 km SW of confluence of Rock Creek and Green River. 14 June 1995. Geoffrey Hammerson. UCM Ancillary Collection (Color Slide 139). Verified by Hobart M. Smith. First record for county and Green River drainage (Cox and Tanner 1995, Snakes of Utah. Publ. Brigham Young Univ., Provo, Utah. 92 pp.). Specific identity is based on anterior coloration and geographic considerations; hemipenes were not examined (see Cole and Hardy 1981. Bull. Am. Mus. Nat. Hist. 171:199–284). Two adults were found about 30 cm apart under debris adjacent to an abandoned ranch building on the flat canyon bottom.

Submitted by **GEOFFREY A. HAMMERSON**, The Nature Conservancy, 68 Landing Road, Higganum, Connecticut 06441, USA, and **AUDREY D. BENEDICT**, Cloud Ridge Naturalists, 8297 Overland Road, Ward, Colorado 80481, USA.

THAMNOPHIS SAURITUS SACKENII (Peninsula Ribbon Snake). BAHAMA ISLANDS: NEW PROVIDENCE ISLAND: Maillis Farm, Adelaide. 4 July 1997. Peter Maillis and Gregory Mahomed. Specimen preserved in alcohol and held in Nassau, Bahamas. Two photographs by S. D. Buckner deposited in the Florida Museum of Natural History herpetological collection (UF Cat. Nos. pending). Verified by Paul Moler. This snake represents the first report of this species from the Bahamas. The snake measured 43 cm SVL, 50.3 cm TL (tip of tail missing). Sex was not determined. It was caught at 1630 h in a garden behind the house of Mrs. A. P. Maillis. A similar snake, possibly the same animal, had been seen previously in a nearby pond. This species is common in south Florida. It was reported that a neighbor had imported exotic trees for his yard, and the specimen may have been transported accidentally to the site in the exotic plants. It is believed that the plants had originated in nurseries from south Florida.

Submitted by **SANDRA D. BUCKNER**, The Bahamas National Trust, Nassau, Bahamas, and **RICHARD FRANZ**, Florida Museum of Natural History, P.O. Box 117800, University of Florida, Gainesville, Florida 32611-7800, USA.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). BAHAMA ISLANDS: ABACO: Port of Marsh Harbour. 27 August 1997. Simeon Pinder. Specimen frozen and held in Nassau, Bahamas. Five photographs by S. D. Buckner deposited in the Florida Museum of Natural History herpetological collection (FSU Cat. Nos. pending). Verified by Paul Moler. This snake represents the first record from the Bahamas. It measures 59 cm SVL, 73.3 cm TL. Sex was not determined. The snake apparently had arrived in a shipment of lumber and was crushed as the lumber was being loaded onto trucks. We presume that this common Florida snake accidentally was transported with the lumber from a port in Florida, as most imported commodities entering the Bahamas originate from ports in that state.

Submitted by **SANDRA D. BUCKNER**, The Bahamas National Trust, Nassau, Bahamas, and **RICHARD FRANZ**, Florida Museum of Natural History, P.O. Box 117800, University of Florida, Gainesville, Florida 32611-7800, USA.

Snakes of Santa Rosa County, Florida: Inadequate Sampling and Serendipity

JEFF BOUNDY
Louisiana Department of Wildlife and Fisheries
P.O. Box 98000, Baton Rouge, Louisiana 70898-9000, USA
e-mail: boundy_jj@wlf.state.la.us

and

FRANK BURBRINK
Museum of Natural Science, Louisiana State University
Baton Rouge, Louisiana 70803, USA
e-mail: fburbri@lsuvm.sncc.lsu.edu

Ashton and Ashton (1988) provide distributions by county for all of the snakes of Florida. It is evident from their maps, when compared with species expected to occur in each county (maps in Conant and Collins 1991), that sampling rate for snakes (species recorded/species expected) varies. The four westernmost panhandle counties all appear to have received moderate and equal sampling: observed/expected ratios are 0.73 for Escambia and Okaloosa counties, 0.68 for Santa Rosa County, and 0.70 for Walton County. Snakes that have not been recorded for each county are not necessarily rare species, and it would be expected that surveys for snakes in either of these counties would reveal a majority of recorded species plus a few unrecorded ones. Our field work in Santa Rosa County revealed a disproportionately large number of species new to the county (8 new vs. 12 recorded). Inadequate sampling for Santa Rosa County is evident from the fact that these additional species of snakes were collected in five trips totalling less than 10 field days, bringing the total observed/expected ratio to 0.88. During field work by the authors (and Alec Knight, Armin Meier, Joseph Slowinski, Ashleigh Smythe, and Tonya Snell), two new species, *Nerodia sipedon* and *Crotalus adamanteus*, were observed but not collected. Five expected species, *Nerodia clarkii, Rhadinaea flavilata, Virginia valeriae, Agkistrodon contortrix*, and *Crotalus horridus*, were not observed. The following species are represented by vouchers in the Louisiana State University Museum of Natural Science (LSUMZ). Species identifications were verified by Douglas Rossman.

Elaphe guttata (Corn Snake). Hwy 191, 4.2 mi S Munson. 30 March 1994. J. Boundy and J. Slowinski. LSUMZ 56373.

Heterodon platirhinos (Eastern Hognose Snake). Blackwater State Forest, 1 mi. on Charley Foster Road from jct. with Sandy Landing Road. 2 April 1996. F. Burbrink and J. Slowinski. LSUMZ 57675.

Heterodon simus (Southern Hognose Snake). 9 mi E on road to Riley's Corner from Rt. 191, ca. 6 mi. S Munson. 24 May 1994. J. Boundy and J. Slowinski. LSUMZ 56507.

Lampropeltis calligaster (Prairie Kingsnake). 6 mi SE Munson on Bud Bass Road, 1 mi. E of jct with Bryant Bridge Road. 24 March 1997. F. Burbrink and A. Meier. LSUMZ 58522.

Lampropeltis triangulum (Milk Snake). Rt. 191, 4.2 mi SW Munson. 24 April 1994. J. Slowinski and A. Knight. LSUMZ 56494. Blackwater State Forest near Munson. 1 April 1996. F. Burbrink, J. Slowinski, and A. Smythe. LSUMZ 58161.

Thamnophis sirtalis (Common Garter Snake). 1 mi N Riley's Corner, ca. 10 air mi. SE of Munson. 24 May 1994. J. Boundy and J. Slowinski. LSUMZ 56508.

New Distributional Records for Reptiles from North Carolina

JEFFREY C. BEANE
North Carolina State Museum of Natural Sciences
P.O. Box 29555, Raleigh, North Carolina 27626-0555, USA
email: jeff_beane@mail.ehnr.state.nc.us

Palmer and Braswell (1995) summarized the geographic distribution of reptiles in North Carolina (USA). I here report additional distributional records, some of which are based on specimens formerly housed in the collections of Duke University and the personal collection of the late Elmer E. Brown, both now on deposit with the North Carolina State Museum of Natural Sciences (NCSM). All specimens were verified by William M. Palmer and Alvin L. Braswell and are deposited at NCSM. New county records and range extensions are based on Palmer and Braswell (1995).

"Previously unvouchered records" are records for counties with previous literature records not supported by voucher specimens.

TESTUDINES

Chelydra serpentina serpentina (Common Snapping Turtle). CRAVEN CO: 5.2 km NNE of Havelock, Cherry Point Marine Base. 20 May 1993. R. R. Swaisgood. NCSM 32595. Previously unvouchered record. Brimley (1915) and Palmer and Braswell (1995) reported sight records for Craven County. FORSYTH CO: 5.5 km ENE of Walkertown. 31 May 1994. J. C. Beane, T. K. Bohannon, D. W. Herman, A. B. Somers, T. J. Thorp, and J. S. Zawadowski. NCSM 36349. New county record. SURRY CO: 8.5 km NW of Mountain Park, Mitchell River. 18 July 1949. J. R. Bailey and J. R. Charles. NCSM 37107. Previously unvouchered record. Palmer and Braswell (1995) reported sight records for Surry County. WILKES CO: 1.3 km SSW of Doughton. 1 June 1996. J. C. Beane, R. A. Davis, D. W. Herman, T. J. Thorp, J. L. Warner, and J. S. Zawadowski. NCSM 41591. New county record.

Kinosternon subrubrum subrubrum (Eastern Mud Turtle). CUMBERLAND CO: 6.4 km WSW of Spring Lake, Fort Bragg Military Reservation, McPherson Creek. 1 July 1992. M. K. Jones. NCSM 31851. New county record. SURRY CO: 5.3 km W of Bottom. 23 May 1994. J. C. Beane, A. B. Somers, T. J. Thorp, and P. Sheridan. NCSM 36131. 5 km N.NE of Mountain Park. 24 June 1995. J. C. Beane, C. K. Cheshire, and S. K. Eanes. NCSM 38717. Northwesternmost localities for North Carolina. Extends range to base of Blue Ridge escarpment and ca. 40 km NW of nearest record in Surry County.

Sternotherus odoratus (Common Musk Turtle). MARTIN CO: 3.7 km S of Hamilton, Conoho Creek. 26 May 1994. A. L. Braswell, R. G. Campbell, and B. L. Beaman. NCSM 36271. Roanoke River near Williamston at Bertie County line. 16 June 1994. V. P. Schneider, J. Fisher, and E. Williams. NCSM 36509. New county records.

Chrysemys picta picta (Eastern Painted Turtle). ANSON CO: 3.4 km ESE of Lilesville. 10 May 1992. A. L. Braswell. NCSM 31632. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Anson County.

Pseudemys concinna concinna (Eastern River Cooter). ROCKINGHAM CO: 0.8 km NNE center of Mayodan, Mayo River. 28 January 1997. G. B. Pottern. NCSM 50066. New county record. Extends range ca. 35 km NNW of nearest records in Guilford County.

Terrapene carolina carolina (Eastern Box Turtle). EDGECOMBE CO: 6.4 km ESE of Battleboro. 12 September 1992. A. L. Braswell et al. NCSM 31860. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Edgecombe County. FORSYTH CO: 3.4 km W of Clemmons along Yadkin River near Davie County line. 22 February 1996. A. B. Somers and K. Bridle. NCSM 40588. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Forsyth County. GASTON CO: Stanley. 1 June 1963. T. Murphy. NCSM 34194; 7 September 1963. T. Murphy. NCSM 34207, 34208, 34253. 4.8 km SE of Stanley. 12 May 1963. T. Murphy. NCSM 34195-34196. 3.2 km SW of Stanley. 7 September 1963. T. Murphy. NCSM 34211; 9 September 1963. T. Murphy. NCSM 34216, 34217, 34252. Previously unvouchered records. Palmer and Braswell (1995) reported a sight record for Gaston County. PERQUIMANS CO: ca. 2.4 km NE of Hertford. 19 June 1964. D. M. Davis et al. NCSM 34227, 34241, 34242. Previously unvouchered records. Palmer and Braswell (1995) reported a sight record for Perquimans County. STOKES CO: 2.8 km WSW of Walnut Cove. 20 May 1994. J. C. Beane, A. B. Somers, and T. J. Thorp. NCSM 36129. 3.5 km ENE of Walnut Cove. 26 March 1996. A. B. Somers, K. Bridle, and M. K. Govus. NCSM 40587. Previously unvouchered records. Palmer and Braswell (1995) reported a sight record for Stokes County.

Trachemys scripta scripta (Yellowbelly Slider). BERTIE-MARTIN COUNTY line: Roanoke River near Williamston. 16 June 1994. V. P. Schneider, J. Fisher, and E. Williams. NCSM 36506-36507. New county records. EDGECOMBE CO: 6.4 km ESE of Battleboro. 12 September 1992. A. L. Braswell et al. NCSM 31854. New county record. GASTON CO: 4.8 km SSE center of Gastonia, floodplain of Anthony Creek. 16 May 1996. S. Tracy. NCSM 41460; 18 May 1996. S. Tracy. NCSM 41641. New county records. Extends range ca. 43 km W of nearest records in Mecklenburg County. NORTHAMPTON CO: 12.9 km WSW of Jackson, Occoneechee Neck. 6-7 May 1997. E. D. Bruner, Jr. NCSM 51279-51280. Previously unvouchered records. Palmer and Braswell (1995) reported sight records for Northampton County.

SAURIA

Anolis carolinensis (Green Anole). BERTIE CO: 1.1 km ENE of Edenhouse, Chowan River at U.S. 17. 17 August 1992. R. W. Laney et al. NCSM 48313. New county record. Extends range ca. 33 km NW of nearest record in Washington County.

Sceloporus undulatus hyacinthinus (Northern Fence Lizard). JONES CO: 4.8 km WNW of Pollocksville. 19 May 1993. A. L. Braswell and R. R. Swaisgood. NCSM 32585. New county record. ROCKINGHAM CO: 8.9 km SW of Stacey. 21 May 1961. R. Highton et al. NCSM 36015. New county record.

Cnemidophorus sexlineatus sexlineatus (Six-lined Racerunner). ASHE CO: ca. 4.8 km N Jefferson, east slope of Phoenix Mountain. 1947. E. E. Brown. NCSM 47750. New county record. Extends range ca. 60 km NW of nearest literature record in Wilkes County and ca. 85 km NW of nearest voucher-supported record in Yadkin County. Partially fills range hiatus shown in Conant and Collins (1991). CLEVELAND CO: 6.8 km WSW of Boiling Springs, along Broad River. 21 June 1994. J. C. Beane et al. NCSM 36603. New county record. IREDELL CO: ca. 3.2 km N of Davidson. 27 June 1949. E. E. Brown. NCSM 47761. Previously unvouchered record. Brown (1992) reported one or more specimens from Iredell County, but did not report specific locality, repository, or catalog numbers. JONES CO: Great Lake, Croatan National Forest. 24 June 1970. J. R. Bailey et al. NCSM 34027 (5 specimens). 4.5 km WNW of Pollocksville near Trent River. 19 May 1993. A. L. Braswell and R. R. Swaisgood. NCSM 32575. New county records. RANDOLPH CO: 14.9 km S of Farmer. 20 May 1992. S. L. and M. S. Alford. NCSM 31685. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Randolph County.

Eumeces fasciatus (Five-lined Skink). ASHE CO: ca. 4.8 km N of Jefferson, east slope of Phoenix Mountain. 1947. E. E. Brown. NCSM 50555. New county record. CABARRUS CO: ca. 8 km E of Davidson, Egg Rock Woods. 25 June 1949. E. E. Brown. NCSM 50556; 3 April 1950. E. E. Brown. NCSM 50558. Previously unvouchered records. Brown (1992) reported one or more specimens from Cabarrus County, but did not report specific locality, repository, or catalog numbers. EDGECOMBE CO: 6.4 km ESE of Battleboro near Swift Creek. 8 July 1991. C. McGrath and J. Alderman. NCSM 31536; 23 August 1991. C. McGrath and J. Alderman. NCSM 31547; 12 September 1992. A. L. Braswell et al. NCSM 31857. New county records. IREDELL CO: ca. 3.2 km N of Davidson. 27 June 1949. E. E. Brown. NCSM 47761. New county record. JONES CO: Trenton, Trenton Mill Pond. 7 October 1979. J. R. Bailey et al. NCSM 41587. New county record.

Eumeces laticeps (Broadhead Skink). DARE CO: Roanoke Island, 4.8 km NW of Manteo, Fort Raleigh National Historic Site property. 17 July 1997. J. C. Beane and Laura H. Terry. NCSM 52491. New county record. First insular record for North Carolina. Extends range ca. 42 km E of nearest records in Tyrrell County.

Scincella lateralis (Ground Skink). BURKE CO: Forest Service road between NC 181 and Table Rock Mountain. 15 May 1949. E. E. Brown. NCSM 52930. Previously unvouchered record. Brown (1992) reported one or more specimens from Burke County, but did not report specific locality, repository, or catalog numbers. IREDELL CO: Mooresville, 169 Scotland Drive. 1 August 1997. J. H. Reynolds. NCSM 52891. New county record. ROWAN CO: Salisbury. 12 November 1949. E. E. Brown. NCSM 52931-52932; 27 October 1951. E. E. Brown. NCSM 52933. Previously unvouchered records. Brown (1992) reported one or more specimens from Rowan County, but did not report specific locality, repository, or catalog numbers.

SERPENTES

Coluber constrictor constrictor (Northern Black Racer). CLEVELAND CO: ca. 1.6 km E of Lawndale. 13 October 1975. E. E. Brown. NCSM 52936. Previously unvouchered record. Brown (1992) reported one or more specimens from Cleveland County, but did not report specific locality, repository, or catalog numbers. Palmer and Braswell (1995) reported a sight record for Cleveland County.

Elaphe guttata guttata (Corn Snake). STOKES CO: Hanging Rock State Park, ca. 3.5 km SE of Moores Springs. 3 October 1993. J. B. Sealy III. NCSM 36639. Previously unvouchered record. Dow and Schwaner (1990) reported a specimen from the same approximate locality, supported by a frozen blood sample and photographs.

Elaphe obsoleta (Eastern Rat Snake). CHOWAN CO: SE Edenton. 14 November 1993. P. R. Trail. NCSM 40082. Previously unvouchered record. Palmer and Braswell (1995) reported sight records for Chowan County. HENDERSON CO: SW Mills River, Pisgah National Forest. 3 June 1968. R. Highton and R. T. Danstedt. NCSM 35658. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Henderson County.

Farancia abacura abacura (Eastern Mud Snake). BERTIE CO: 6.9 km SSW of Woodard, Middle Prong of Three Sisters Creek off Broad Creek. 2 April 1996. R. W. Gaul, Jr., Trip Lamb, and J. Horton. NCSM 40495. New county record.

Farancia erytrogramma erytrogramma (Rainbow Snake). HARNETT CO: 2.7 km N of Bunnlevel near Upper Little River. 8 July 1997. H. A. Randolph. NCSM 52615. New county record. ONSLOW CO: Jacksonville, Mill Creek drainage. Date and collector not specified. NCSM 34870-34873. Previously unvouchered records. Palmer and Braswell (1995) reported a sight record for Onslow County.

Lampropeltis calligaster rhombomaculata (Mole Kingsnake). CATAWBA CO: 5.8 km SSW Sherrills Ford. Ca. 10 September 1996. W. Gilbert. NCSM 44465. New county record.

Lampropeltis getula getula (Eastern Kingsnake). GRANVILLE CO: 4.3 km ESE of Providence. 22 June 1997. W. H. Rowland, Jr. NCSM 52092. New county record. SURRY CO: 5.2 km N of Mountain Park at Mitchell River. 4 June 1993. S. K. Eanes. NCSM 32668. Previously unvouchered record. Brown (1992) and Palmer and Braswell (1995) reported sight records for Surry County. WILKES CO: 1.3 km SSW of Doughton. 10 May 1996. T. J. Thorp, J. C. Beane, and J. S. Zawadowski. NCSM color slide JCB 96-782. New county record.

Lampropeltis triangulum triangulum (Eastern Milk Snake). SURRY CO: vicinity of Mountain Park. Early 1980s. S. K. Eanes. NCSM 32066. Previously unvouchered record. Palmer and Braswell (1995) reported a specimen from Surry County supported by a photograph.

Lampropeltis triangulum elapsoides (Scarlet Kingsnake). CHOWAN CO: Edenton, Blount St. near Edenton Bay. Mid-August 1992. C. Burns. NCSM 32065. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Chowan County.

Nerodia erythrogaster erythrogaster (Redbelly Water Snake). BERTIE CO: 1.4 km SE of Grabtown. 9 June 1992. R. W. Gaul, Jr. NCSM 31810. New county record. ANSON CO: 6.4 km SE of White Store, Bell Creek. 18 March 1990. R. G. Arndt et al. NCSM 32021. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Anson County. This record extends range 28 km W of that sight record and ca. 56 km WSW of nearest voucher-supported record in Richmond County.

Nerodia sipedon sipedon (Northern Water Snake). GUILFORD CO: 2.4 km SE of Stokesdale, Rock Branch. 20 September 1995. W. M. Palmer, A. L. Kyles, R. Pegram, and L. Earnest. NCSM 39516. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Guilford County. ROWAN CO: 4.0 km SSE of Mount Ulla at Sills Creek. 23 March 1964. E. E. Brown. NCSM 52937. Previously unvouchered record. Brown (1992) reported one or more specimens from Rowan County, but did not report specific locality, repository, or catalog numbers.

Nerodia taxispilota (Brown Water Snake). LEE CO: 4.8 km NE of Cumnock, Deep River at Chatham County line. 7 June 1996. J. C. Turner. NCSM 41772. New county record. Extends range ca. 33 km NNE and 44 km WNW of nearest records in Moore and Harnett counties, respectively.

Opheodrys aestivus (Rough Green Snake). LINCOLN CO: ca. 9.7 km W of Lincolnton. 13 October 1975. E. E. Brown. NCSM 52934. Previously unvouchered record. Brown (1992) reported one or more specimens from Lincoln County, but did not report specific locality, repository, or catalog numbers.

Regina rigida rigida (Glossy Crayfish Snake). COLUMBUS CO: Lake Waccamaw. 3 September 1981. E. E. Brown. NCSM 52883. New county record.

Regina septemvittata (Queen Snake). DAVIDSON CO: 6 km SE of Jackson Hill, Beaverdam Creek. 10 September 1961. T. and P. Murphy. NCSM 33722. 4.8 km N of Denton, Lick Creek. 26 August 1962. T. Murphy and M. Bailey. NCSM 33732-33733. New county records. NASH CO: 2.7 km NNW center of Rocky Mount, Tar River at Battle Park. 15 April 1996. M. E. Ruff. NCSM 40795. New county record. Extends range to edge of Coastal Plain and ca. 82 km E of nearest records in Vance and Wake counties.

Storeria occipitomaculata occipitomaculata (Northern Redbelly Snake). CALDWELL CO: Globe. 9 August 1954. E. E. Brown. NCSM 52436. Previously unvouchered record. Brown (1992) reported one or more specimens from Caldwell County, but did not report specific locality, repository, or catalog numbers. ROCKINGHAM CO: 6.9 km SW of Ellisboro. 27 March 1992. T. J. Morgan. NCSM 31627. New county record.

Thamnophis sauritus sauritus (Eastern Ribbon Snake). NORTHAMPTON CO: 12.9 km WSW of Jackson. 27 April 1997. E. D. Bruner, Jr. NCSM 50924. New county record. SCOTLAND CO: Camp Mackall Military Reservation. 10 August 1985. J. C. Beane and T. J. Thorp. NCSM 25863. Previously unvouchered record. Palmer and Braswell (1995) reported a sight record for Scotland County.

Thamnophis sirtalis sirtalis (Eastern Garter Snake). CLEVELAND CO: ca. 1.6 km E of Fallston. 13 October 1975. E. E. Brown. NCSM 52935. Previously unvouchered record. Brown (1992) reported one or more specimens from Cleveland County, but did not report specific locality, repository, or catalog numbers. SURRY CO: 2.6 km E of Level Cross. 8 July 1992. A. B. Somers. NCSM 31773. New county record.

Micrurus fulvius fulvius (Eastern Coral Snake). PENDER CO: 3.6 km WSW of Atkinson, Cone's Folly. April 1995. Bob Murray. NCSM 37878. Previously unvouchered record. Brimley (1922) and Palmer and Braswell (1995) reported a sight record from near Topsail Inlet in Pender County.

Acknowledgments.—I thank the many individuals whose field work resulted in new distributional records. S. D. Busack, W. M. Palmer, and A. L. Braswell reviewed an earlier draft of the manuscript.

BOOK REVIEWS

A Research Guide to the Lizards of Cuyabeno, by Laurie J. Vitt and Stella de la Torre. 1996. Monograph 1, Museo de Zoología (QCAZ), Centro de Bioversidad y Ambiente Pontificia Universidad Católica del Ecuador. 165 pp, 36 color plates. Softcover. US $30.00. ISBN 9978-77-042-9.

JOSEPH R. MENDELSON III

Natural History Museum, and Department of Systematics and Ecology
The University of Kansas, Lawrence, Kansas 66045-2454, USA

Present address: Department of Biology, Utah State University
Logan, Utah 84322-5305, USA

This book is divided into two major sections: 1) an introduction including description of the study site and its four vegetation types, and a review of basic methods for field ecologists, and 2) species accounts for the 25 species of lizards (including one amphisbaenid) known to occur at Cuyabeno. The text is presented in English and Spanish and color plates of all species are grouped at the end of the book. A prologue by Dr. Tjitte de Vries, director of the Centro de Bioversidad y Ambiente at Pontificia Universidad Católica del Ecuador, indicates that this book is intended as a foundation for future studies at Cuyabeno and as a field guide for ecotourists. Cuyabeno is an equatorial lowland rainforest site that is being managed for research in ecology and sustainable resource exploitation.

Vitt and de la Torre have taken an interesting and novel approach with this book. As the title indicates, this is, in fact, a *guide* for research—and not necessarily only for Amazonian lizards. As such, the introduction serves as an excellent primer for field ecological studies. The authors emphasize several points in this section including the crucial importance of collection and deposition of voucher specimens in active museums. Researchers also are encouraged to take advantage of the unique opportunity at the moment of capture to gather a suite of basic ecological data that include body, ambient, and substrate temperatures, as well as basic observations of behavior, weather, and habitat. These data, kept in association with the voucher specimens, may complement the dietary and reproductive data that can be recovered later through dissection, and will maximize the scientific value of each specimen. Samples from the authors' own database for *Norops nitens* provide good examples of a practical format and proof that the authors make the effort to collect these various data themselves. The "Basic Ecological Data Collection" section of the introduction is the most unique, and the strongest, contribution of

this book. I would consider assigning this section as "required reading" for students developing undergraduate, master's, or *licenciatura* projects involving field work. Throughout the book, the authors emphasize the critical importance of considering phylogeny (= history) in all ecological studies. They also offer well-founded advice, based upon their considerable experience, regarding sample sizes and the suitability of different species for the investigation of various ecological questions—indeed, potentially exciting research projects are suggested throughout the book.

The authors' summary of ecological data gathering techniques could have been expanded to include more discussion of trapping techniques—viz., pitfall traps, which I have found to be quite effective for capturing some of the more elusive leaf litter gymnophthalmids. Night collection of sleeping lizards is mentioned only briefly in a few species accounts—certainly one cannot gather much in the way of behavioral or active temperature data from sleeping lizards, but it is the only way by which I have collected such elusive species as *Dactyloa transversalis.* Also, a brief illustrated guide to preservation techniques would have augmented this otherwise complete section—poorly prepared voucher specimens are only slightly better than none at all.

The species accounts and color plates comprise the remainder of the book. Species are partitioned into sections by family, each prefaced by nice pen-and-ink illustrations of representative species drawn from one of the plates. Vitt and de la Torre are appropriately explicit regarding the source of the taxonomy they have chosen with respect to generic allocation of species (e.g., Frost 1992, for Tropiduridae; Guyer and Savage 1986, for anolines) and Avila-Pires (1995) is cited often as the source for other taxonomic information. The taxonomy used by the authors is consistent throughout, except that *Norops nitens* (sensu Avila-Pires 1995) is referred to as *Norops chrysolepis* in the caption for Plate 13.

Each species account includes a black and white photograph, a brief introduction, and the following sections: Activity, Size and Morphology, Foraging and Diet, Escape, Reproduction, Description, and Comment. The authors state in the Introduction that their intent was to "provide enough information on identification of species that students and other researchers working in the area will have no difficulty identifying lizard species." Thus, the description section in each account is neither a full description nor diagnosis of the species, but rather an assemblage of character descriptions that should aid in identification of individuals in the hand. In a few cases in which two or more similar species occur in the area, explicit diagnostic comparisons are made. I found the lack of uniformity among the descriptions frustrating; however, I must admit that, along with the illustrations provided, most people should be able to correctly identify the lizard species considered in this book. The Foraging and Diet and Reproduction sections, in most cases provide data collected by the authors at Cuyabeno, augmented by references to other works (e.g., Duellman 1978; Dixon and Soini 1986). The remaining sections provide general information that should prove useful to persons trying to locate, capture, and identify lizards at Cuyabeno (or elsewhere). The Size and Morphology section presents data on sizes of individuals from Cuyabeno and, in most cases, little in the way of morphological information beyond general comments on the habitus of the species. In some cases (e.g., *Alopoglossus angulatus)* no "morphological" information is presented; in others the information is misleading. For example, both *Iphisa elegans* and *Kentropyx pelviceps* are described as "fusiform;" these lizards bear little resemblance to one another. Inclusion of a key to the lizard species of Cuyabeno would have been helpful. Also, a more complete treatment of species that quite possibly occur at Cuyabeno, but have not yet been documented, would inevitably have been helpful to some future researchers. A few such species (e.g., *Enyalioides cofanorum)* are mentioned in passing, but others that probably occur there (e.g., *Bachia trisnale),* are not.

I found a few typographical errors, but none of them critical to the sense of the text. I found the Spanish translation to be accurate with respect to the English text. The black and white photographs nicely augment the species accounts and seem to be of high quality; however, the halftones were not of high resolution and some are not as useful as they could have been. Most of the color plates are excellent. The photograph of *Pseudogonatodes guianensis* is a bit dark—although this is how they actually appear in the hand. The photograph of the male *Gonatodes concinnatus* is also a bit dark and does not show well the distinctive orange cephalic coloration that is described in the text.

Vitt and de la Torre have produced a unique and useful book. The species accounts, given their stated purpose, are useful, and the introduction is a nice summary of how to do modern field ecology. As such, this book contributes far more than the relatively useless checklists that reserves, parks, and even countries, commonly provide, and breaks beyond the traditional "see and identify" boundary of field guides by suggesting how and why to conduct research on these lizards. Finally, the authors are to be commended for taking the initiative to produce a bilingual volume—certainly not all researchers and ecotourists are *gringos.*

ISBN 1-56098-648-4 (hardcover), 1-56098-649-2 (softcover).

MARK WITWER

1029 Sunhigh Drive, West Chester, Pennsylvania 19380, USA

Those of us who do educational programs about snakes for children and civic groups know how many questions are out there! This book capitalizes on that interest, using a question-and-answer format to answer the most common questions about snakes. The species and topics discussed are global in scope, but many of the examples used will be most familiar to North American readers.

The book is nicely produced. The softcover edition has a sturdy glossy cover, attractively designed around an excellent close-up photograph of *Rhabdophis subminiatus* by Richard Bartlett. The pages are securely bound, the print dark and easily read, the text conveniently arranged into sections and broken up by attractive graphics. The overall effect is to invite a reader to browse.

The content is divided into five chapters (Snake Facts, Folk Tales, Giant Snakes: Big and Biggest, Snakebite, Snakes and Us) and each chapter has multiple subdivisions. Separating the chapters into "bite-sized" chunks is good pedagogy, and helps to make the information accessible.

The first and longest (73 pages) chapter answers over fifty general questions about snakes (e.g., "Do Snakes Hear?", "Can Snakes Change Colors?", "When Did the First Snake Appear?"). The answers contain a wealth of moderately detailed information, and are sometimes cross-referenced with each other and with other chapters. The information is accurate and up-to-date (e.g., snakes can hear airborne sounds; constriction does not kill primarily by suffocation; snakes may not all have indeterminate growth). The vocabulary in this chapter borders on semitechnical, but some terms are immediately clarified in parentheses. A passage from the answer to "How Do Snakes Spend the Winter?" is illustrative: "Most snakes are probably facultative hibernators, whose winter inactivity is triggered by external cues such as dropping air temperatures. Some, however, appear to be obligatory hibernators, in which some endogenous (internal) control mechanism—a biological clock—initiates winter inactivity at approximately the same time each year." Terms not explained in parentheses may be found in the glossary (e.g., "facultative" and "obligatory" in the passage above) but this is not always the case. The vocabulary in this chapter will be difficult for some readers, particularly younger ones.

Chapter Two is the shortest of the five chapters (10 pages) and addresses common myths about snakes (e.g., "Do Snakes Hypnotize Their Prey?", "Do Venomous and Nonvenomous Snakes Interbreed?"). The answers here are less technical, and include some interesting historical and cultural information.

Chapter Three (25 pages) departs from the question-and-answer format to discuss the world's larger snakes. The expected large boids and king cobra (*Ophiophagus hannah*) are profiled here, in addition to many others (taipans, mambas, asian ratsnakes, rattlesnakes, etc.). The language is nontechnical and a large number of interesting species are covered—certainly most of the species of high interest to the general public. I found very few errors in the book, but three appear in this chapter. First, both the caption and accompanying text identify Figure 3.15, a Gaboon Viper (*Bitis gabonica*), as a Rhinoceros Viper (*Bitis nasicornis*). A correctly identified *Bitis nasicornis* appears in color plate 10B. Second, the caption to Figure 3.11 gives the maximum known length of the black mamba (*Dendroaspis polylepis*) as 3 meters. The accompanying text and Appendix 2 both give the maximum length as 4.5 meters. Spawls and Branch (1995) give the maximum length for this species as "probably about 3.5 m." Third, page 117 states that *Thelotornis kirtlandii* is one of four colubrids which has caused human fatalities, although these fatalities are now attributed to *Thelotornis capensis* (Spawls and Branch 1995).

Chapter Four (29 pages) explores venoms (e.g., "What Is Venom?", "Can Venom Be Used as Medicine?"), venomous snakes (e.g., "How Many Snakes Are Venomous?"), and snakebite (e.g., "How Do Fangs Work?", "If Bitten, What Next?"). This material is thorough and easily read. The chapter also contains some excellent tables and line drawings. Table 4.1 is a two-page list of venom components, described by their actions and the taxa possessing them. Table 4.3 lists the LD_{50}'s and venom yields of 81 species. The line drawings throughout the book are good to excellent in quality and serve to clarify the text. In this chapter, the drawings of representative skulls and maxillae (Figures 4.8 and 4.10) of aglyphous, opisthoglyphous, proteroglyphous, and solenoglyphous snakes are outstanding.

The short (14 pages) final chapter provides a very strong conclusion to the book. Threats facing snakes and their importance to humans worldwide are highlighted first, including several useful historical examples of the importance of snakes in rodent control. This is followed by a thorough discussion of why snakes appear in our homes and lawns, with good advice on what to do about it. A slightly edited version of these first sections of Chapter Five would make an excellent flyer for distribution to the public. Putting this information into the hands of landowners and those using natural areas might have significant local impacts for snake conservation. (Are any herpetological organizations out there looking for a worthy project?) The next section addresses the question, "Should I Keep a Snake as a Pet?". Because they have seen so much poor care, the authors do not believe that any amphibian or reptile should be kept as a pet. They explain their position clearly, and graciously ("We also know many people who take good care of their snakes ..."). Then, to their credit, they go on to address those who are determined to keep snakes, giving the best two-page summary of advice to beginners that I have read anywhere (pp.150–151). The final brief sections concern herpetological careers.

Throughout all of the chapters, black and white photographs are used to good effect. Most are of very good quality and, like the line drawings, serve to clarify the text. There are very few of these photographs that I would have left out.

The 64 color photographs are grouped as 24 plates, all found on 16 glossy pages located about one fourth of the way through the book. Although most of these photographs are small, many are technically very good (some are excellent); some also illustrate significant biological phenomena (e.g., coral snake mimicry; color variation in *Sistrurus m. miliarius*). The quality is not uniform, however; quite a few appear underexposed, overexposed, or faded. Redundancy with the black and white photographs occurs at least twice: the same black mamba head shot shown in Plate 7C is in black and white in Figure 3.11, and two almost identical African birdsnake photographs (apparently of the same snake) appear in Plate 16D and Figure 1.25 .

The chapters are followed by five appendices which contain a great deal of information in convenient list form. Included are the taxonomic hierarchy of snakes to the subfamily level, the number of genera and species in each family, body sizes of a large number of species, comparative speeds of some snakes and other creatures (including humans), reproductive data for a number of snake species, and a short list (ten) of professional and regional herpetological organizations.

Following the appendices are a glossary, general bibliography, and subject bibliography. The glossary is moderate in length, but considering the general audience and the vocabulary level in much of the book, it could be longer. The general bibliography contains 27 books on snakes and general herpetology published between 1957 and 1994. The subject bibliography (a short list of references for most sections of the five chapters) is particulary useful, directing the interested reader to books and papers while freeing the text from citations.

The final sections of the book are a taxonomic index (by common name) and a subject index. A great deal of effort obviously went into constructing the detailed taxonomic index. (Reading a page or two of it will convince reluctant students of the value of scientific names!) Given the general audience of the book, it was wise to index common names; but many readers will miss having a standard taxonomic index as well. The subject index is surprisingly brief (about two full pages) and should have been expanded. "Mimicry" is in the title of the first color plate, and I went looking for it under "m" in the subject index. No luck. Neither was it under "d" for defense. I finally found it as a subheading under

color. And although Duvernoy's gland is in the glossary, I could not find it in the index at all.

Despite its minor flaws, this book is a gold mine of useful information, conveniently and attractively arranged, and deserves wide readership. Members of the general public with an interest in or curiosity about snakes will learn much from it. Science educators will find it a useful reference; anyone who regularly speaks or writes about snakes for the public should have a copy. Professional herpetologists may find it useful in helping to frame concise answers to commonly asked questions. While the $49 hardcover price seems high for a book of this length, the softcover price is half that much and well worth it. The softcover edition's lower price, attractive cover, and inviting question-and-answer format makes it an excellent book to take to programs and hold up as recommended reading for interested listeners.

WINSTON CARD
Department of Herpetology, Dallas Zoo
650 South R. L. Thornton Freeway (I-35E), Dallas, Texas 75203, USA
e-mail: winstoncard@sprintmail.com

There are numerous manuals, popular articles, and videos dedicated to the care of green iguanas (*Iguana iguana*) in captivity (Bartlett and Bartlett 1995; Coborn 1994; de Vosjoli 1992; Ferrel 1992; Frye 1995; Frye and Townsend 1993; Roberts and Roberts 1976). Indeed, this area has been discussed in the popular literature ad nauseum. Owners of pet iguanas are now confronted with yet another iguana husbandry manual that is no less than 600 pages in length.

As the title suggests, this book was designed specifically for individuals interested in iguanas as pets. The first 98 pages are dedicated to simplified descriptions of iguanas in mythology, morphology, behavior, and some information concerning the author. The next 240 pages cover various aspects of husbandry. The last three sections (each of about 100 pages) cover medical troubleshooting, domestication, and breeding.

Ten appendices are also included at the end of the book covering a variety of subject matters related to iguana husbandry. Perhaps the most useful information is contained in Appendix D, which provides detailed instructions on how to construct an indoor iguana habitat.

James Hatfield is to be commended in his efforts to compile information for this voluminous work. The author traveled extensively and apparently spent many hours with various academic authorities on *Iguana iguana*. This fact is stated several times in the text.

Although this book is rather large, it contains little new information. The author does an inadequate job clarifying existing controversies, such as those relating to nutrition and reproduction. Although these topics are discussed, Hatfield offers no tangible evidence to support many of his opinions that contradict what has been published elsewhere. Many of the criticisms outlined for other iguana husbandry manuals (see Rodda 1994), can also be applied here.

Chapter Eight, concerning domesticating green iguanas, is perhaps the most "unique" portion of this book. Outlined here are techniques for training captive iguanas to beg for food, correct bad behaviors, proper petting techniques, and even the proper way to hand feed pet iguanas. You might also apply these same techniques to train your wayward German Shepherd!

The author tends to be verbose, anthropomorphic, and prone to exaggerations throughout the text. For example, in Chapter Nine a story concerning the killing of an adult "Fer-de-Lance" by the author with a machete to save two terrorized iguanas in Costa Rica is related. Hatfield claims to have deduced the emotional state of the two animals by "the contorted looks" on their faces.

Repeated reference is made to an iguana questionnaire that the author apparently distributed to other iguana owners, veterinarians, and perhaps a few academic herpetologists. However, nowhere in the book is a complete analysis of the data obtained from these questionnaires presented. Comments attributed to respondents litter the 600 pages of text. The quotes appear to serve no real purpose and tend to be distracting. Removal of the comments from the text would reduce the size of this book significantly.

I cannot recommend this book for reasons outlined above. Readers will find little pertinent information not already available in one of the smaller manuals. In fact, one will be required to wade through a great deal of superfluous text to get to the desired husbandry information.

Recent years have seen the publication of several valuable works on the biology of monitor lizards (e.g., Bennet 1995; De Lisle 1996; King and Green 1993), reflecting increased scholarly and popular interest in these species. This self-published book is a new edition of the 1991 original, which due to some unfortunate errors and inaccuracies was not well received. The authors make it clear that they were motivated to reissue this work in part to correct these earlier difficulties; unfortunately they were not wholly successful. For example, the authors note that, "Far too many writers reproduce unquestioned the previous exaggerations

of the species' size, though only one specimen has ever [sic] documented as larger than 9 ft, 6 in (2.85 m)." While the tone of this statement is admirable, it is difficult to reconcile with the back cover of the book which reads, "Komodo the 10 foot long reptile."

My disappointment with the book stems from a deeper concern. The authors state as their goal to provide a popularized version of Auffenberg's (1981) classic *The Behavioral Ecology of the Komodo Monitor.* Is such a popularization necessary? Auffenberg's work is very readable and most of it is comprehensible to an interested non-professional reader. Furthermore, although Auffenberg's book is a benchmark study and still of significant value, it is now 16 years old. The Lutzs have incorporated little of the subsequent scientific literature on *Varanus komodoensis*, including studies on behavior (Horn 1985), thermoregulation and energetics (Green et al. 1991), and locomotion (Suzuki and Hamada, 1992; Suzuki et al. 1991). If a popularization of Auffenberg's work was desirable it is not evident that the Lutzs are in the best position to carry it out. This book leaves one with the sense that the authors lack a well-developed familiarity with *V. komodoensis*: their understanding of the Komodo dragon seems to be based on visits to several zoos and a single visit to Komodo Island where, judging by their repeated criticisms of the park guides, the authors never felt at ease.

The apparent unfamiliarity with these animals leaves a telling mark on this book—*V. komodoensis* is treated independently of all other varanids. This was certainly not the case with Auffenberg's work, nor is it the case in the other recent books on *Varanus*. Even in a book dedicated to one species, as this one is, some more general context is critical. Treating *V. komodoensis* independently leaves the Lutzs prone to make statements of dubious validity. For example, they state that in contrast to the Komodo dragon, "... other lizard species usually carry their bodies closer to the ground and spend much of their movement time running." They go on to remark that, "The dragon's tongue tips are not far enough apart to make their directional reading work well, so it swings its head back and forth to improve its reception." Both of these statements, and several others, are provided without any support or citation.

To me the most interesting aspect of this book was the chronology of captive Komodo dragons. The differing travel routes, prosperity, and fates of these animals are fairly well presented. Nonetheless, the Lutzs' contention that early attempts to maintain captive specimens caused the animals to lead, "nasty, brutish, and short" lives is not well supported by the information they present. One of the earliest captive specimens, Buchben, lived 17 years in captivity during which time she laid several clutches of eggs.

The book ends with a lengthy discussion of the captive breeding of *V. komodoensis* in the United States; in fact, the Lutzs state that this new information was one of the reasons they decided to reissue this book. But of the 21 text pages devoted to this topic, 16 are taken verbatim from publications of the National Zoo. Much of the remainder is a table of the location of living captive specimens, which differs from information presented in the text. The National Zoo's successful captive breeding of *V. komodoensis* is certainly a noteworthy accomplishment; interested individuals would seem best served by obtaining information directly from the National Zoo. Furthermore, the Lutzs' claim that the captive breeding in the U.S. has, "... assured the continued survival of this unique reptile" seems at odds with the passing reference they make to the fact that the Gembira Loka Zoo and Botanical Gardens has been breeding Komodo dragons since at least 1968.

Readers interested in the biology of the Komodo dragon would be better served by purchasing one of the other recent works on monitor lizards, or finding a copy of Auffenberg's (1981) book. Individuals interested in the conservation and captive breeding of these interesting animals should probably contact one of the zoos involved.

HINRICH KAISER

Department of Biology, La Sierra University
Riverside, California 92515, USA
e-mail: hkaiser@lasierra.edu

As soon as I heard about the publication of this volume, I knew I needed to have it. Why? First of all, having been exposed to the incredible *Eleutherodactylus* fauna in the tropics, these species and their natural history can give excellent pointers to outsiders and insiders alike about the ecology and biogeography of the region in general. Secondly, how often do two seasoned war horses of herpetology get together anymore to produce tomes for posterity? Lastly, I have worked on *Eleutherodactylus* (eleuths for short) for a while, so naturally I looked to this book for some additional insights.

Although the book's title limits its scope geographically, the authors add a lot of information on eleuths that goes well beyond western Ecuador. Thus, the statement on the back cover, announcing that the book I was holding was "the definite work on the largest genus of vertebrates" is true and an excellent advertising slogan. I found hidden in its pages a wealth of information, and I believe these descriptions, data, and miscellaneous bits of information to be the result of a lot of dedication, an attitude of "never quit," and a lot of hard work. Just for putting such a comprehensive monograph together, the authors must be commended.

As far as the content is concerned, there are few deviations from some of the authors' previous collaborations (e.g., Lynch and Duellman 1980) or individually produced taxonomic surveys (e.g., Duellman 1970; Lynch 1979, 1981). Noteworthy are ex-

tended character descriptions that are not just limited to their separate section (pp. 24–41) but which permeate the species accounts that comprise the main body of the book. Furthermore, the authors provide an appendix (pp. 219–234) listing all applied species names for *Eleutherodactylus* including synonymies, and a gazetteer (pp. 208–218) for localities in western Ecuador. Keeping with the style of their previous taxonomic surveys, the book is heavy on systematic commentary; the authors provide good reason for this, however, by reiterating (p. 2) that eleuths should be "ideal subjects for ecological studies" but that researchers have not used them "because these frogs have been a notoriously difficult group taxonomically." In my opinion, a thorough reading of this volume might help people discover a fascination for eleuths, and an appreciation beyond the "little brown frog" denominator.

The book is divided into four main sections. The first one details the abiotic factors important to the western Ecuadorian eleuth fauna, but this information is also applicable to research on any number of other organisms in that neck of the woods. The latitudinal profiles (Fig. 3) are a welcome addition to a geography section in a systematics text like this, and they help those unfamiliar with the extreme Andean topography to visualize the terrain. The subdivisions on physiography, river systems, bioclimate regimes, vegetation, and even geologic and climatic history are accompanied by a variety of useful tables and figures, and some key primary literature on these topics is later supplemented by the authors' own experience in each of the species accounts. I found the last subdivision of this section, on human environmental modifications, timely, yet unexpected and somewhat poignant. It is unfortunately true that we have arrived at a time where comments such as these are necessary, not only for their historical value in a biogeographic assessment, but because deforestation and environmental mismanagement now set the stage in a lot of places in the tropics for fundamental changes in the behavior of biota. The term "requiem," as used in reference to extirpation during habitat loss (I have heard it in reference to primary rain forests in the West Indies as well as Central America), is rapidly becoming cliché—an abomination.

The section on systematics is the largest in the book and comprises detailed descriptions of western Ecuadorian eleuths, including the description of nine new species. A very welcome inclusion in this section is a 30-page treatise on eleuth characters and definitions of the relevant species groupings (series and subgenera). This is a revision and expansion of the character lists the authors published previously (e.g., Lynch 1979; Lynch and Duellman 1980), and it gets eleuth systematists up to date. Although a lot of this information is very useful, and required reading for anyone attempting to describe a new *Eleutherodactylus* adequately, I am surprised that there is no mention of the variability in vocalizations, at least for those species for which calls are known. This has been a deficiency in many descriptions of *Eleutherodactylus*, sometimes simply because the specimens were found in museums long after having been collected. There are very few instances where the authors mention calls in the species accounts, although many frogs were apparently observed during times of breeding activity.

The key to the species is comprehensive and its appearance in Spanish, in addition to English, is appropriate. Species accounts and maps are of high quality, and it is a relief to see that some of the detailed field notes which each of the authors has taken over decades and which have been hidden from view have now made it into print. For eleuth enthusiasts like myself, the 64 color plates alone are reason enough to get this volume into the library. I remember rummaging around in the University of Kansas Herp Slide Collection of eleuths and looked at the color diversity of what some, including myself, have called "small brown frogs"—my view was drastically changed on that count! The photo choices are excellent, and the quality of reproduction challenges the high gloss of TFH.

Section three, on ecology, could probably stand on its own as a descriptive paper on "the *Eleutherodactylus* way of life" (p. 150). The authors present data collected over time from nine eleuth communities, and this can certainly serve as an example for studying eleuth communities elsewhere. Because the section includes very little in the way of testing on the four addressed variables (abundance, body size, food, microhabitat), it should be encouraging to anyone to see how much work still needs to be completed. I tremendously enjoyed the five figures (Figs. 58–62) on eleuth microhabitats, showing the positions of individual species in the landscape, and I remember seeing similar ones for Caribbean *Anolis*. This type of information might take some of the guesswork out of finding a species by its call. The authors present a thorough discussion of their information, and I concur with their hope that, given this more accessible taxonomy, more detailed studies can now be undertaken.

The last major section concerns the biogeography of western Ecuadorian eleuths. Here the authors, who previously have produced seminal papers on biogeography (e.g., Duellman 1979; Lynch 1988), formulate some solid biogeographic hypotheses for the current distribution of the *Eleutherodactylus* fauna, by bioclimatic regimes, altitude, and regional geography. Again, tables, graphs, and maps abound and some of these are particularly useful to forge a link between large-scale abiotic factors (e.g., altitude, latitude) and speciation. Examples given include the distributions of several sets of sister species (Figs. 71–72, 74–78), as well as of several species groups (Figs. 79–84). The clincher for their biogeographic argument is a regional speciation model (Figs. 85, 86) which the authors show to be mostly congruent with biogeographic patterns observed in other taxa. I consider this section very successful in design and content, and I think similarly thorough scenarios need to be developed for many other regions.

At this point I may have lost some readers. Why bother reviewing if you have nothing negative to say at all? I feel it is not as important to see what's wrong than what's right in research these days. In particular, I wanted to see whether Lynch and Duellman, household names in herpetology, can throw together a piece of work like this and create a new standard. Quantity isn't equivalent to quality, and both authors freely admit that during all these years of publishing in high quantities a few mistakes went by unnoticed. Therefore, high page count doesn't impress anyone anymore. I think in this book the pages are well invested, the overall quality is excellent, and it is indeed the new standard for traditional eleuth research. It should not be missing on your shelf, so get it before KU runs out.

Bangor LL57 2UW, Wales, UK
e-mail: w.wuster@bangor.ac.uk

Interest in Southeast Asian herpetology has been increasing steadily over the last few decades. This has been reflected in a growing number of comprehensive publications on the snakes of several countries, such as Cambodia (Saint Girons 1972), Thailand (Cox 1991) and Malaysia (Tweedie 1983), and several further works that are in preparation. However, several countries have remained insufficiently covered by this expanding literature. Foremost among these is Indonesia. The last comprehensive lists for that country are those of de Rooij (1917) and de Haas (1950), both of which are now outdated. Several works have been published on the faunas of various islands (in den Bosch 1985; van Hoesel 1959; Hodges 1993; Stuebing 1991), but the herpetofauna of Sumatra has received scant attention. The publication of David and Vogel's book on the snakes of Sumatra is thus a valuable addition to the literature on the herpetofauna of southeast Asia in general, and Indonesia in particular.

After the foreword and introduction, the book starts with eight pages on the geography and herpetofauna of Sumatra, including a brief history of past herpetological research on the island. This is followed by four pages on materials and methods and a list of the 127 snake species recorded from the island. A substantial part of the introduction is devoted to a discussion of the high species richness of the Indonesian snake fauna and its causes, with much emphasis being placed on the effect of physical, ecological and climatic diversity. It seems strange that the most obvious cause, namely the fact that Indonesia straddles two major faunal regions and consequently includes much of the diversity of both, is not taken into consideration.

The main part of the text consists of the individual species accounts. These contain the following information: primary systematic data, including original name, describer, year, reference and type locality (including current name, where appropriate); a partial synonymy containing synonyms specifically relevant to Sumatra; taxonomic comments, addressing problems of nomenclature or systematics; locality records on Sumatra; total range of taxon; ecological notes on the Sumatran population (principally published altitude data); natural history notes; and a list of other subspecies and their ranges in the case of polytypic taxa.

It is worth noting what is not included in the species accounts: there are no descriptions of the individual species (although differences between some pairs of similar species are mentioned in some cases), and the types are not cited. In both cases, the reader is told that this information is "readily available in the literature." This reviewer feels that a list of name-bearing types would have been useful, and would not have required much additional space. The relevant literature may be "readily available" to those with large museum libraries a few yards down the corridor, but this is not the case for many university-based researchers.

This systematic part is followed by an annotated list of species which had been previously reported for Sumatra, but probably do not occur there, and a key to the families, and, within families, to all species. The key includes the species of doubtful occurrence, which will facilitate their identification if their presence on Sumatra is eventually confirmed. The keys rely mostly on scalation characters, which will facilitate the identification of living specimens. In some cases, simpler characters might have been found: the pattern of *Daboia russellii* would probably be a better character for distinguishing it from other vipers than the number of dorsal scale rows! In the case of the Elapidae, the key is potentially confusing at point 4, as Sumatran specimens of *Naja sumatrana* are not necessarily uniformly black: many specimens show light crossbars, and some are various shades of brown or tan rather than black.

The impressive bibliography includes approximately 500 references, some annotated. The bibliography is generally very up-to-date, with large numbers of recent references. The final part of the book consists of a very useful gazetteer of the island, which also includes current spellings of older names.

Illustrations come in the shape of ink drawings of the head of several species (generally excellent, but excessive shading obscures important scalation details in some, e.g., the supralabials in *Trimeresurus borneensis* on p. 161), and a section of 33 small color photographs, representing nine habitats and 18 species. The quality and choice of photographs is disappointing: the plates appear distinctly faded in the two copies of the book that I have seen, and the quality of several of the shots is rather poor. Presumably this is due to the fact that photographs of Sumatran specimens are rather thin on the ground.

This book represents a welcome preliminary account of the snake fauna of Sumatra. It will be useful for anyone concerned with the herpetofauna of that island, and the gazetteer and comprehensive bibliography will make it useful to anyone with natural history interests in Indonesia.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1998 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
1998 ANNUAL MEETING

together with

AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS
THE HERPETOLOGISTS' LEAGUE
CANADIAN ASSOCIATION OF HERPETOLOGISTS
16 – 22 July 1998
University of Guelph, Ontario, Canada

Keynote Address: "THE EVOLUTION OF MORPHOLOGICAL NOVELTIES," by Sharon Emerson, The Herpetologists' League Distinguished Herpetologist (University of Utah).

Symposium: "RECENT ADVANCES IN ANURAN COMMUNICATION: A SYMPOSIUM HONORING DR. STAN RAND."*Organizer:* Michael J. Ryan, Clark Hubbs Regents Professor in Zoology, Department of Zoology, University of Texas, Austin Texas 78712, USA; e-mail: mryan@mail.utexas.edu. Tel: (512) 471-5078; Fax: (512) 471-9651.

Symposium: "PHENOLOGY OF FISHES, AMPHIBIANS, AND REPTILES: INTEGRATING ORGANISM-LEVEL AND POPULATION-LEVEL PERSPECTIVES." *Organizers*: Eric Schultz and Kentwood Wells, Department of Ecology and Evolutionary Biology, University of Connecticut, Storrs, Connecticut 06269-3042, USA.

Symposium: "TO FREEZE OR NOT TO FREEZE: AMPHIBIANS AND REPTILES IN THE COLD." *Organizer:* Kenneth B. Storey, Department of Biology, Carleton University, 1125 Colonel By Drive, Ottawa, Ontario, Canada K1S 5B6; e-mail: kbstorey@ccs.carleton.ca. Tel: (613) 520-3678; Fax: (613) 520-4497.

Symposium: "HERPETOLOGY IN THE LAB AND FIELD: A SYMPOSIUM IN RECOGNITION OF THE CAREER OF RONALD A. BRANDON." *Organizers:* Steve Reilly, Department of Biological Sciences, Ohio University, Athens, Ohio 45701, USA; e-mail: reilly@ohio.edu. Tel: (614) 593-3343, and Ronn Altig, Drawer GY, Department of Biological Sciences, Mississippi State University, Mississippi State, Mississippi 39762, USA. e-mail: rga2@Ra.MsState.edu. Tel. (601) 325-7561.

Conservation Forum/Point-Counterpoint: "CITES: BENEFIT OR HINDRANCE TO THE CONSERVATION OF AMPHIBIANS AND REPTILES." *Participants:* Sue Lieberman (U.S. Fish and Wildlife Service), Brian Bowen (University of Florida). *Organizer:* C. Kenneth Dodd, Jr., Florida Caribbean Science Center, U.S. Geological Survey, 7920 N.W. 71st Street, Gainesville, Florida 32653, USA. e-mail: Ken_Dodd@usgs.gov.

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day throughout the conference.

Student Paper Awards: Seibert Prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the December 1997 issue of *HR* for details.

Student Travel Grants: Ten travel grants of US $200 each will be available for SSAR student members. Refer to the December 1997 issue of *HR* for details.

Multimedia Presentations: "HERPETOLOGY OF THE WEST" and "AMPHIBIANS OF THE APPALACHIANS" by David Dennis and Eric Juterbock; "HERPETOLOGICAL NAMESAKES" by Kraig Adler and David Dennis.

Social Activities: General Reception at the University Center Building, SSAR Auction, Picnic at Guelph Lake, ROMMY II, Graduate Student Reception, and ASIH Banquet.

Field Trips: Metro Toronto Zoo, Long Point Provincial park, Royal Ontario Museum, Niagara Falls and Winery.

Live Exhibit: Live amphibians and reptiles of Ontario will be on display and available for viewing and photo sessions.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Costs: Pre-registration $170.00 Canadian (approx. US $120) regular, $85.00 CAN (approx. US $60) student/accompanying person. After April 1, 1998, costs are $220.00 CAN (approx. US $155) regular, $125.00 CAN (approx. US $88) student/accompanying person.

Further Details: See December 1997 issue of *HR* (pp. 169–171). Meeting Announcement and Call for Papers was mailed to all Canadian, U.S., and Mexican members of SSAR in January 1998. Overseas members wishing to receive this information may do so by contacting *Tana McDaniel, Department of Zoology, University of Guelph, Guelph, Ontario, Canada N1G 2W1. Tel: (519) 824-4120 ext. 6260; fax: (519) 767-1656; e-mail: meeting@uoguelph.ca.* Please visit the meeting web site at http://www.uoguelph.ca/~ichsherp for additional and updated information.

About Our Cover: *Uroplatus phantasticus*

Uroplatus phantasticus is an aptly named endemic gekkonid from Madagascar. It has been dubbed the 'satanic' leaftail gecko in reference to its fleshy, horn-like ocular tufts, and the belief by some Malagasy that these lizards are in fact little devils incarnate. Inhabiting mid-elevation moist forests of the east-central portion of the country, they are nocturnal prowlers among slender, sparsely-leafed, woody plants and saplings within one to two meters of the ground. The flattened heads and membranous fringes lining the head, body, and legs of most of its congeners, which aid in eliminating telltale shadows as they sleep adhered to the trunks of trees by day, are absent in *U. phantasticus* and its smaller-tailed, close relative *U. ebenaui*.

Described by Boulenger in 1888, *Uroplatus phantasticus* often has been relegated to the synonomy of *U. ebenaui* (e.g., Bauer and Russell. 1989. J. Nat. Hist. 23:169–203). However, recent collections in northern Madagascar by Nussbaum and Raxworthy (1995. Copeia 1995:118–124) suggest that this is indeed a species distinct from *U. ebenaui*.

Nine species were included within the genus *Uroplatus* in the most recent summary of the Madagascar herpetofauna (Glaw and Vences 1994. A Fieldguide to the Amphibians and Reptiles of Madagascar. 2nd ed., Cologne. 480 pp.). A tenth, *U. malama*, a smoother-skinned, southern representative of the *ebenaui* species group, has since been described (Nussbaum and Raxworthy 1995, *op. cit.*). It seems likely that other species await discovery.

The cover image, of an adult male *Uroplatus phantasticus* ca. 85 mm in total length, was taken by **Bill Love** at the private farm of Soafiavy Export in Antananarivo. Olaf Pronk, the director, assisted him in posing and recording it photographically, as he has done with numerous other seldom-seen endemic herps during visits spanning the past seven years. Lighting was provided by two Nikon SB26 Speedlights in TTL mode, both mounted on a Stroboframe dual flash macro bracket with the arms extended about 20 cm above and below a Nikon F90X camera body. A 105 mm AF Micro-Nikkor lens caught the shot on Fujichrome Velvia (ASA 50), exposed at f32 while handheld.

About his photography and our cover shot, Bill says: "I shoot mostly straightforward I.D.-style photos of herps. I think the additional artistic appeal of this image is enhanced by three factors: the low eye-level view highlighted the 'horns' in silhouette and made an exciting, almost confrontational pose; only the immediate area of the subject was lit adequately, negating incidental daylight and background scenery beyond flash range to artificially create an appropriate nocturnal scene; and the brilliance of the previous shot left the lizard's pupils contracted, producing the bizarre, extra-terrestrial look of the huge eyes."

Bill is a writer of popular herpetological articles, and several regular advice/information columns in *Reptiles*, *The Vivarium*, and *Reptilia* magazines. His slides frequently appear in books, periodicals, calendars, zoo graphics, and commercial advertising. His main passions, natural herp photography and everything Malagasy, have been combined by lecturing about and leading ecotours to Madagascar through his company, Blue Chameleon Ventures.

Separation and imaging of Love's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as President for 1999) ..... *Victor Hutchison.*

Secretary ..... *Ellen Censky (unopposed).*

Treasurer ..... *Robert Aldridge (unopposed).*

Directors ..... *C. Kenneth Dodd, Jr., and Claudia Luke.*

NEWSNOTES

Summer Course on Biology of Plethodontid Salamanders

"Biology of Plethodontid Salamanders" will be taught at Highlands Biological Station June 1–12, 1998. The instructor will be Stephen G. Tilley. The southern Appalachians are renowned for the diversity of the salamander fauna. This course acquaints students with plethodontid salamanders and shows how studies of these animals have enhanced our understanding of a series of major evolutionary and ecological topics. This is a lecture, field, and laboratory course that will include discussions of original research papers. Three semester hours credit at the advanced undergraduate/graduate level are available through either Western Carolina University or the University of North Carolina at Chapel Hill. For further information contact: *Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA. Tel. (704) 526-2602, fax (704) 526-2797, e-mail: hibio@wcu.edu.*

Southwestern Research Station Volunteer Positions for 1998

Approximately 30 volunteer positions are open in 1998 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

Zoo Internship Available

The Kentucky Reptile Zoo, a nonprofit organization, is seeking a student intern for the 1998 spring, summer, and fall seasons. The zoo is an educational exhibit, and a reptile breeding and venom research facility located near Kentucky's Red River Gorge and Natural Bridge State Park. The intern will assist in the captive maintenance of the zoo's reptile collection, collect admissions to the exhibit, give interpretive talks and interact with the public, assist with educational outreach programs, and perform other duties as assigned. In addition, the intern will be responsible for the completion of at least one research project related to the field of herpetology. The intern will not be involved in the handling of any venomous reptiles.

Desirable qualifications include a willingness to handle snakes and other reptiles on a daily basis, ability to communicate effectively with people, writing skills, orientation to details, and self-motivation. Students majoring in the biological or natural sciences are preferred. Former interns have arranged for academic credit with their colleges or universities. Benefits include experience with the most extensive and diverse collection of snakes in the area, housing, and $55/week to cover expenses. Personal transportation is recommended. Starting dates are flexible, but a minimum commitment of three months covering Spring (March–May), Summer (June–August), or Fall (September–November) is required. Application deadlines are Febuary 1 (Spring), April 1 (Summer), and June 1 (Fall).

To apply, send a cover letter and resume to: *Jim Dykes, Internship Coordinator, Kentucky Reptile Zoo, 1275 Natural Bridge Road, Slade, Kentucky 40376, USA.*

Announcement

The Museum of Natural Science at Louisiana State University is seeking a collections-oriented herpetologist to curate its collection of nearly 80,000 amphibian and reptile specimens, teach appropriate graduate and undergraduate courses, and conduct an active and productive research program. Review of applications will begin in early April, and the anticipated starting date for the position is 4 January 1999. For further information, contact Dr. Douglas A. Rossman, Chair, Search Committee, Museum of Natural Science, 119 Foster Hall, Louisiana State University, Baton Rouge, Louisiana 70803, USA. Telephone (504) 388-3081; fax (504) 388-3075. Position availability is contingent upon budgetary approval. EO/AA Employer.

LEGISLATION & CONSERVATION

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. Please direct all communications to the Section Editor.

USA: US Fish and Wildlife Service: Effective 4 November 1997 the USFWS listed northern populations (ranging from New York and Massachusetts south to Maryland) of the bog turtle (*Clemmys muhlenbergii*) as threatened under the Endangered Species Act. The listing also designates southern populations as threatened due to similarity of appearance. Under this listing southern populations are exempt from incidental take during otherwise lawful activities. Additionally, it was determined that "any benefit potentially provided by designation of critical habitat for the bog turtle would be outweighed by the increase in threats to the species and its habitat from illegal collecting and vandalism caused by such a designation...." The final rule concerning this listing can be found in Federal Register Vol. 62 No. 213. pp. 59605–56923.

For additional information, contact: *Carole Copeyon, Pennsylvania Field Office, U.S. Fish and Wildlife Service, 315 South Allen Street, Suite 322, State College, Pennsylvania 16801, USA*

USA: US Fish and Wildlife Service: The USFWS has proposed threatened species protection for the flatwoods salamander (*Ambystoma cingulatum*). The flatwoods salamander is endemic to the longleaf pine flatwoods of the southeastern U.S. coastal plain. The principal threat to this species is loss of its native habitat, which has declined to less than 20% of its original distribution. Historically, these salamanders ranged from Alabama, south to north-central Florida, and north into Georgia and southern South Carolina; however, none have been captured in Alabama since 1981. Since 1990, all historical records for which adequate locality data were given, have been surveyed. Of these 97 sites, only 12 had flatwoods salamanders present. Further surveys of appropriate habitat throughout their range have located only 47 remaining populations of flatwoods salamanders.

For additional information concerning the proposal, contact: *Linda LaClaire, Jackson Field Office, U.S. Fish and Wildlife Service, 6578 Dogwood View Parkway, Suite A, Jackson, Mississippi 39213, USA. e-mail: linda_laclaire@fws.gov.*

USA: Ohio: The Ohio Department of Natural Resources Division of Wildlife has recently adopted new regulations concerning the purchase or sale of any amphibian or reptile taken in Ohio. The regulations also provide special protection for wood turtles (*Clemmys insculpta*). The regulation states that, "...It shall be unlawful to buy sell or offer for sale any reptile or amphibian which was taken in Ohio without first obtaining permission from the chief of the Division of Wildlife. Provided further it shall be unlawful to buy, sell, transport, or possess wood turtles, without first obtaining permission from the chief of the Division of Wildlife."

For more information, contact: *Dr. Martin J. Rosenberg, Department of Biology, Case Western Reserve University, 10900 Euclid Avenue, Cleveland, Ohio 44106-7080, USA.*

New Zealand: On 4 July 1997, agents from the Police and Wildlife Enforcement Group apprehended one Freddy Angel on charges of smuggling tuatara (*Sphenodon punctatus*) from Stephens Island. Mr. Angel pleaded guilty in a preliminary hearing on 7 July to the following charges: conspiring with Anson Wong (a wildlife trader from Penang, Malaysia) to trade in endangered species; possession of four tuatara; and unlawfully hunting or killing protected species. Mr. Angel previously had served a five-year prison sentence for stealing tuatara from the Southland Museum and removing tuatara illegally from Stephens Island. Unfortunately, as this case demonstrates, the black-market value (estimated at US $6,000–9,000 each for tuatara) of many protected amphibians and reptiles outweighs the risk of being caught.

Tuatara are the sole extant members of the ancient order Rhynchocephalia and are protected under the TIES (Trade In Endangered Species) act and CITES Appendix I. Congratulations to New Zealand's law enforcement responsible for the capture. For more information about this case contact: *Phil Bishop, Department of Zoology, University of Otago, P.O. Box 56, Dunedin, New Zealand. e-mail: phillip.bishop@stonebow.otago.ac.nz.*

MEETINGS

Meetings Calendar

18 April 1998—21st Annual All Florida Herpetology Conference, University of Florida, Gainesville. *Refer to conference announcement elsewhere in this issue for details.*

1–3 June 1998—Biodiversity and Conservation of Amphibians and Reptiles of Tropical Forests: An International Symposium. Hanoi, Vietnam. Contact: Natalia Ananjeva (St. Petersburg, Russia), e-mail: nbanorus@glas.apc.org.

12–15 June 1998—Highlands Conference on Plethodontid Salamanders, Highlands Biological Station, Highlands, North Carolina, USA. To be placed on the mailing list, or to up-date your address, please send your name, address, and numbers (phone, FAX, e-mail) to: Plethodontid Conference, Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA, or send an e-mail message to Judy Hill at: JHILL@wpoff.wcu.edu. Additional information: http://www.wcu.edu/hibio.

25–27 June 1998—22nd Annual Meeting of the International Herpetological Symposium, Inc., Holiday Inn-Cincinnati Airport, Cincinnati, Ohio, USA. Contacts: Stan Draper, IHS Secretary, P.O. Box 16444, Salt Lake City, Utah 84114-0444, USA; e-mail: sdraper@npsp.com; or Pete Strimple, Liaison Committee Chair, 5310 Sultana Drive, Cincinnati, Ohio 45238, USA; tel. (513) 451-2392; e-mail: pds0404@aol.com.

16–22 July 1998—41st Annual Meeting, Society for the Study of Amphibians and Reptiles; 46th Annual Meeting of The Herpetologists' League; 78th Annual Meeting, American Society of Ichthyologists and Herpetologists. Hosted by the University of Guelph, Guelph, Ontario, Canada. *Refer to meeting announcement in this issue for details.*

1–5 September 1998—Third International Asian Herpetological Meeting, Almaty, Kazakhstan. To receive the First Announcement and Preliminary Registration Form, please contact one of the meeting organizers: Dr. Tatjana Dujsebayeva, Department of Biology, Kazakh State University, Al-Farabi Prospect, 71, Almaty, 480078, Kazakhstan; tel. (3272) 472677; fax (3272) 472609; e-mail: zool@plague.almaty.kz; Dr. Natalia Ananjeva, Department of Herpetology, Zoological Institute, Universitatskaja nab., 1, Saint-Petersburg, 199034, Russia; tel. (812) 2180711; fax (812) 2182941; e-mail: anb@zisp.spb.su; or Dr. Theodore Papenfuss, Asiatic Herpetological Research, Museum of Vertebrate Zoology, University of California, Berkeley, CA 94720, USA; tel. (510) 642-3567; fax (510) 643-8238; e-mail: asiaherp@uclink2.berkeley.edu.

13–17 May 1999—Fourth International Symposium on Isolated Vertebrate Communities in the Tropics, Bonn, Germany. Hosted by the Zoologisches Forschungsinstitut und Museum Alexander Koenig. To receive announcements and to obtain further information, please contact: Prof. Dr. W. Böhme, Adenauerallee 160, 53113 Bonn, Germany; tel. +49 228 91 22 250, fax ++49 228 216 979, e-mail: r.hutterer.zfmk@uni-bonn.de.

Special Notice on *ALYTES*

The International Society for the Study and Conservation of Amphibians (ISSCA) announces a special offer to institutions (universities, libraries, museums, associations, etc.). ISSCA will donate a complete set of Volumes 1–14 (1982–1996) of its journal *ALYTES*, an international journal devoted to amphibian biology, to any institution that a) agrees to take the journal for 5 years, and b) pays postage on sending the journal to the institution. In North America, the cost would be US $640.00 (subscription plus surface mail shipping). Checks payable to "ISSCA" should be sent to: *Dr. Mark Wygoda, Department of Biological and Environmental Sciences, P.O. Box 92000, McNeese State University, Lake Charles, Louisiana 70609, USA.*

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Christopher Sheil or Anne Maglia (postal and e-mail addresses on inside front cover). Readers are encouraged to send us your comments concerning Current Research. We are most interested in knowing what you'd like to see here, and how we can improve this section's utility for all readers.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are being listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Five New Gekkonid Genera

The genus *Phyllodactylus* has long been systematically problematical. Despite the removal of several monophyletic groups the genus remains polyphyletic. Through the evaluation of morphological features and allozymes, Bauer et al. found that Old World *Phyllodactylus* are not closely related to New World *Phyllodactylus*. Further, Old World species as a unit do not form a demonstrably monophyletic group. In order to resolve the Old

World species, the authors described five new genera as well as resurrecting another genus. Redescriptions and diagnoses are provided for two other currently recognized genera. The authors restrict *Phyllodactylus* to New World species only (although the monophyly of this group is not strongly established), with the Madagascan species *P. brevipes* remaining *incertae sedis*.

BAUER, A. M., D. A. GOOD, AND W. R. BRANCH. 1997. The taxonomy of the southern African leaf-toed geckos (Squamata: Gekkonidae), with a review of Old World "*Phyllodactylus*" and the description of five new genera. Proc. Calif. Acad. Sci. 49(14):447–497.

Rhacodactylus Phylogenetics

Good et al. examined phylogenetic relationships of the New Caledonian giant geckos of the genus *Rhacodactylus*. Both allozyme and morphological data yield largely congruent patterns of relationships. A "total evidence" approach was used, incorporating 13 allozyme and 29 morphological characters, to determine a single most-parsimonius phylogenetic tree. In addition to the relationships within the genus *Rhacodactylus*, the authors tentatively regard *Pseudothecadactylus* as valid because allozyme data conflict strongly with morphological data that suggest that these geckos evolved from within *Rhacodactylus*.

GOOD, D. A., A. M. BAUER, AND R. A. SADLIER. 1997. Allozyme evidence for the phylogeny of giant New Caledonian geckos (Squamata: Diplodactylidae: *Rhacodactylus*), with comments on the status of *R. leachianus henkeli*. Aust. J. Zool. 45:317–330.

Chelonian Population Structure

Dodd recently tested the hypotheses that in chelonian species with sexual size dimorphism, the smaller sex will mature at a smaller size and a younger age than the larger sex, sex ratios should be biased in favor of the earlier maturing sex, and deviations from a 1:1 sex ratio result from maturation of the smaller sex at a younger age. The data used to test these hypotheses were collected from 1991 to 1995 on an insular population of Florida box turtles (*Terrapene carolina*). Contrary to predictions, the earlier maturing sex grew to larger sizes than the late maturing sex. A sex ratio imbalance did exist, but did not result from faster maturation of the smaller sex.

DODD, C. K., JR. 1997. Population structure and the evolution of sexual size dimorphism and sex ratios in an insular population of Florida box turtles (*Terrapene carolina bauri*). Can. J. Zool. 75:1495–1507.

Catalogue of Amphibians and Reptiles in the Silesian Museum

The Silesian Museum in Opava was founded in 1814. In 1945 most of the zoological collection in the museum was destroyed, leaving few scientifically valuable specimens. Post-war herpetological collections contain several hundred vouchers from the Czech Republic as well as material from Slovakia, Balkan Peninsula, Russia, Africa, Asia, and America. Gvozdik and Benes have taken advantage of this collection in their recent catalogue of amphibians and reptiles from two Czech Republic regions, northern Moravia and Silesia.

GVOZDIK, L., AND B. BENES. 1997. Amphibians and reptiles of northern Moravia and Silesia, Czech Republic, in the Silesian Museum, Opava. Cas. Slez. Muz. Opava. 46:23–49.

21ST ANNUAL ALL FLORIDA HERPETOLOGY CONFERENCE

Co-sponsored by The Florida Museum of Natural History and The Gainesville Herpetological Society

18 April 1998
The University of Florida, Gainesville, Florida

Registration: $15 per person (before 13 April); $17 per person (after 13 April).

Speakers include: Keynoters William Duellman and Peter Pritchard, Susan Donoghue, Neil Ford, Michael Grace, Kathy Love, Charles Peterson, and Scott Stahl.

Also featured: Florida Herpetology Graduate Student Symposium, organized by Richard Franz; Florida Live Snake Exhibit, organized by Kevin Enge; Captive Breeder Exhibits, Herp Art, Books, and Jewelry, and Evening Barbeque and Auction.

For information or to register, contact: *David Auth, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, or call (352) 392-3264.*

Developmental Constraints

For many years researchers at the Department of Vertebrate Zoology, St. Petersburg State University have been studying developmental constraints of the anuran sacrum. The purpose of these studies is to examine the range of variability of a morphological structure in its whole spectrum of possibilities. To date several papers and at least one book have been published, mostly on ranid frogs. Recently, Malashichev published an analysis of the sacrum variability in *Bombina*.

MALASHICHEV, Y. B. 1997. Qualitative analysis of sacrum variability in some *Bombina* species. *In* W. Böhme, W. Bischoff and T. Ziegler, (ed.). Herpetologia Bonnensis, pp. 257–263.

Chelonian Phylogeny

Both molecular and morphological data for the 23 major lineages of living turtles and seven key fossil taxa were used to examine the phylogeny of chelonians. This approach resulted in a very well-resolved tree with only a few of the deep branches within the Cryptodira left as an unresolved polytomy. The addition of fossil data provided little added resolution to the tree and resulted in a sharp decline in bootstrap proportions for nodes near the fossils.

SHAFFER, H. B., P. MEYLAN, AND M. L. MCKNIGHT. 1997. Test of turtle phylogeny: Molecular, morphological, and paleontological approaches. Syst. Biol. 46(2):235–268.

Phrynosoma Biogeography and Taxonomy

The short-horned lizard (*Phrynosoma douglasi*) ranges throughout much of western North America. Zamudio et al. analyzed mtDNA sequences from 38 populations of *P. douglasi* to deter-

mine the biogeographic and phylogenetic relationships within this species. They found that *P. douglasi* as currently recognized is paraphyletic with respect to *P. ditmarsi*. In light of their data the authors discuss the taxonomic implications for this group.

ZAMUDIO, K. R., K. B. JONES, AND R. H. WARD. 1997. Molecular systematics of short-horned lizards: biogeography and taxonomy of a widespread species complex. Syst. Biol. 46(2):284–305.

Advances in Amphibian Research in the Former Soviet Union

With the breakup of the USSR, a large amount of information on the biology of amphibians, formerly published in state subsidized journals, no longer had a publishing outlet. As years passed, studies on the biology of amphibians expanded into new and exciting research fields. Clearly, a new journal was needed to serve the growing number of amphibian biologists within the territory of the former Soviet Union, as well as to introduce western biologists to the breadth of research now underway. In 1996, I was asked by Dr. Sergius Kuzmin of the Russian Academy of Sciences to assist with the production of the first two issues of such a new journal, *Advances in Amphibian Research in the Former Soviet Union*.

AARFSU publishes original research papers on the systematics, biogeography, ecology, evolution, behavior, morphology, genetics, physiology, paleontology, and conservation of amphibians throughout the huge territory occupied by the former Soviet Union. Papers are published in English allowing dissemination of important research results to an international audience. The response to the first two issues has been enthusiastic among Russian and former USSR amphibian biologists, hence the decision to continue the publication as a research journal. The wide range of topics covered in the first two issues have provided non-USSR biologists with a valuable insight into Nearctic amphibian research and to a literature that is still very difficult to obtain.

Sergius and I hope these first two issues deepen our understanding of amphibian biology both within the former USSR and among western scientists inasmuch as we often share common problems in the study and conservation of amphibians and their habitats. The modest subscription price will ensure that future issues maintain the high quality we hope is evident in volumes 1 and 2.—*Submitted by C. Kenneth Dodd, Jr., Biological Resources Division, U.S. Geological Survey, 7920 N.W. 71st Street, Gainesville, Florida 32653, USA.*

"Roger Conant is the nation's senior herpetologist, the doyen of an unrelentingly intense group of specialists whose enchantment by reptiles adds interest to their profession as well as their subjects. Scientist, editor and author (of more than 240 papers and twelve books), Dr. Conant's encyclopedic knowledge of 'herps,' zoos and the care and mentoring of more herpetologists is as instructive as it is legendary. But Conant's long, rich life has been so complex that it could only be appreciated with a field guide, so he has produced one.

A marvelous tour de Conant!"

INSTITUTIONAL PROFILE

Herpetology in Southern Ontario

JAMES P. BOGART
Department of Zoology, University of Guelph
Guelph, Ontario, Canada N1G 2W1

and
ROBERT MURPHY
Centre for Biodiversity and Conservation Biology
Royal Ontario Museum, 100 Queen's Park, Toronto, Ontario Canada M5S 2C6

The Ontario herpetological fauna consists of 24 species of amphibians and 25 reptile species. Most reach the northern limits of their range in southern or central Ontario. Our fauna is by no means rich but does provide interesting distributional and physiological questions. Long-term monitoring of distributional and life history information in Ontario is mostly done by an extensive network of volunteers. The resulting Ontario Herpetofaunal Summary was started in 1984 and this successful monitoring program was profiled in Heyer et al. (1994). Ontario enjoys a healthy interaction of amateur and professional herpetologists in the Universities, Museums, the Ontario Ministry of Natural Resources, the Canadian Wildlife Service, the Canadian Forest Service, the World Wildlife Fund (Canada) and regional herpetological societies. Input from these agencies and societies have been used by DAPCAN (Declining amphibian populations task force, Canada) and COSEWIC (Committee on the status of endangered wildlife in Canada) to flag species and habitats that are of special concern in Ontario and in Canada (Green 1997).

The University of Guelph

The University of Guelph is a research-intensive institution with more than 1500 graduate students. Although the campus is more than a century old, the University was established in 1964 as a diversification and expansion of three Colleges (Agricultural, Veterinary, Home Economics) of the University of Toronto. The expansion included colleges of Arts, Biological Sciences, Family and Consumer Studies, Physical and Engineering Science, and Social Science. The 344-hectare campus combines traditional buildings dating back to the last century with contemporary concrete and glass structures.

Herpetology at Guelph

Several faculty members at Guelph use amphibians and reptiles in their research. Dr. Dale Smith in the Ontario Veterinary College studied healing in snakes and assists with radio-telemetry work; Dr. Steve Scadding investigates regeneration in the Axolotl; Dr. Don Stephens studies amphibian muscle physiology; and Dr. Pat Wright studies metabolism in frogs. Herpetological research is the primary focus of Drs. Bogart and Brooks in the Department of Zoology.

Dr. Bogart and his students work on a range of herpetological problems. Two Ph.D. students are studying evolution at the species level. Andrew Chek is studying tropical speciation through an examination of vocalizations and sequence-derived phylogenies of wide ranging species groups of hylid frogs in Brazil. Leslie Rye is examining introgression at the nuclear and mitochondrial DNA level in the garter snakes of Canada and eastern North America. The MSc students being advised by Dr. Bogart include Dave Britton who is examining spatial relationships and diversity of amphibians and reptiles of the Georgian Bay Islands in Lake Huron. Janine Glaser is studying the effects of aerial spraying of gylphosate herbicide on wood frog populations in forest plantations in northern Ontario. Tana McDaniel is studying ecological partitioning in leopard and pickerel frogs in eastern Canada, and Josh Feltham is attempting to derive a sequenced-based phylogeny for hybrid salamanders of the genus *Ambystoma*. Dr. Bogart is continuing his research on polyploid amphibians. He has recently investigated tetraploid sand frogs of the genus *Tomopterna* with Dr. Alan Channing in southern Africa and finally completed a monograph on the *Ambystoma* hybrids in New England and New York with Dr. Michael Klemens.

Dr. Bogart and his students have undertaken a project that attempts to incorporate data bases from the Ontario Herpetofaunal Summary and the Canadian Forest Service into a Geographical Landscape System (GLS) analysis for amphibians and reptiles in Ontario. The past and present locality information for amphibians and reptiles in Ontario is used to examine ranges, follow declines, and monitor trends over time. This system has other distinct advantages. By overlaying temperature profiles, water courses, elevation gradients, soil substrate, forest types and cover, or any of a wide variety of possible environmental or ecological correlates, the statistical probabilities that a geographic position would be a favorable habitat for an individual amphibian or reptile can be estimated. This project is a collaborative effort that involves Mike Oldham, of the Ontario Heritage Foundation who has incorporated the Ontario Hepetofaunal data and screens the new locality information, Dan McKenney of the Canadian Forest Service in Sault Ste. Marie who does his magic with computer analyses and graphics, and students at Guelph who, often in conjunction with their other projects, gather locality information, test statistical "hot" spots, and ground truth anomalous information. It is expected that the project will eventually be expanded and carry itself through the efforts of interested people and agencies. A web page (http://fcor2.glfc.forestry.ca/english/res/herp/herp.html) describes the project and has been set up as a first attempt for a dynamic Ontario Herpetofaunal Atlas.

Dr. Ron Brooks is continuing his long-term and intensive monitoring of amphibian and reptilian populations in Ontario. Investigations of life history strategies, population ecology, conservation biology, and reproduction of reptiles and amphibians form the major thrust of the research activities of Ron and his students. Much of Ron's research is being done at the Wildlife Research Station in Algonquin Provincial Park in Central Ontario. The

Calling male gray treefrog (*Hyla versicolor*), one of the species involved in Bogart's studies of polyploid amphibians.

projects being done in the Park include: Dave Cunnington's analysis of optimal egg size of the spotted salamander in lakes with and without predatory fish; Shane de Solla's investigation of home range and containment levels of the snapping turtle; Lisa Enright's investigations of the effects of selective logging on forest amphibian communities; Kevin Judge's examination of the importance of metapopulation dynamics to the persistence of amphibian populations; Cam MacDonald's study of age-related reproductive success and population ecology of the bullfrog; and Janet Lochead's investigation of pre-ovulatory parental investment of the snapping turtle. Nicky Koper has conducted a laboratory study on the relative importance of light and food on the growth of the painted turtle. Jon Edmonds is examining the population ecology of the stinkpot turtle in Georgian Bay and Rob Wilson is studying habitat selection and thermoregulation of the fox snake populations around the Great Lakes.

Herpetology at the Royal Ontario Museum

The Royal Ontario Museum is located adjacent to the University of Toronto in vibrant downtown Toronto. It is Canada's largest and most prestigious museum. Unlike most Canadian museums, the ROM's mandate is not restricted to the province. The museum is also quite unusual in combining earth and life sciences along with art and archaeology. Its collections are international in scope. A visit to the museum reveals the phenomenal Chinese collections, including three 12th and 13th century Buddhist Temple paintings, and a Ming Dynasty tomb, among other treasures.

The herpetological collections at the ROM are maintained by one shared technician, a team of highly dedicated volunteers, and the two permanent staff members, Ross MacCulloch (Assistant Curator) and Bob Murphy (Sr. Curator), the first academically-trained Curator (Ph.D.-type) of Herpetology in the museum. In 1984 the herpetology collections at the ROM numbered about 14,000 specimens, and most of these were from Ontario. The collection of amphibians and reptiles now numbers more than 40,000 specimens, plus an additional 35,000 samples of frozen tissues. The resource has become international in scope, and much of the preserved material is backed-up by the extensive array of frozen tissues. Significant collections have been made in Australia, Liberia, Guyana, México, southern California, and the Caucasus—southern Russia (Daghestan), Armenia, and Georgia. Smaller collections have been made in other places, such as Peru and the Philippine Islands. However, the single greatest strength of the collection is Vietnam, where, since 1994, we have collected more than 10,000 specimens.

The research facilities of the ROM are quite adequate for phylogenetic investigations. The ROM has its own x-ray and video digitizing facilities for morphological investigations, as well as a cytology lab. Nearby at the University of Toronto, the ROM-based research group has access to a state-of-the-art flow cytometry facility, SEM, and similar technical laboratories. Bob's molecular lab is equipped for simultaneously running 20 starch gels (cheap nuclear gene information), five radiation-based sequencing gels, and automated DNA sequencing; they don't buy data from a core facility. Macintosh G-3 266 MHz and Dell Pentium Pro 300 MHz computers facilitate efficient data evaluation. The lab has frequent international visitors. For example, Liu Wanzhao is currently visiting from the Kunming Institute of Zoology, China; soon Drs. Nikolai Orlov and Natasha Ananjeva will be on board from the Zoological Institute of St. Petersburg, Russia (repeat visitors), and then Gustavo Aguirre-L. and Georgina Santos-B. from México will visit, Gus for his third time. Sometimes there are visitors from America.

Dave Britton with one of his study subjects, a fox snake (*Elaphe vulpina*), at a site in Georgian Bay.

Ross MacCulloch is concentrating his field-based efforts on herpetofaunal diversity surveys in Guyana. His laboratory research has concentrated on allozymes of Caucasian lacertas. These forays include investigating the number of clones in uniparental species, population differentiation among widely-distributed species, and taxonomic status of isolated subspecies. And there is no doubt Ross is the king of flow cytometry in the lab.

Bob's research remains scattered across the globe—go ahead and try to find him—and equally varied in topic. If there is a central theme to the work (and such is highly debatable) then it's in molecular systematics, conservation genetics, methods of molecular data gathering and cladistic analysis, and international evaluations of Guiness. Molecular macroevolutionary topics include the phylogeny of rattlesnakes (a study of about 3000 bp of sequence data, and including all but three species of rattlesnakes), Baja California reptile genetics (forever), the phylogeny and evolution of the sympatric occurrence of ecotypes of Vietnamese frogs, and phylogenetic constraints on the evolution of unisexuality in reptiles. Microevolutionary research continues in the population genetics of Caucasian lacertas (in collaboration with Ilya Darevsky and crew, Ross, and others), and ever-present Baja projects. Most population genetics works are developing into true conservation genetics studies via involvement in conservation policy and strategies. Research into methods of data analysis continue in the form of ivory-tower development and application of randomization methods for searching and locating character covariation (which is not the same as philosophically flawed confidence estimation), as well as documenting the absurdity of using frequency (allozyme and morphological) information of phylogeny estimation—just wait for ROMMY II! However, such thought-inspiring debate has taken a back seat to biodiversity documentation and conservation efforts.

As a faculty member at the University of Toronto, Bob currently sponsors several graduate and undergraduate honors research students. Most senior, Jinzhong Fu is studying the evolution of lacertid lizards. His research has concentrated on DNA sequence data, spanned the micro- macroevolutionary boundary, and is now entering the realm of the phylogenetic perspective of lizard ecology. Fu will complete his dissertation in 1998. Amy Lathrop has undertaken a daunting doctoral dissertation topic, the evolution of *Megophrys*. Her study includes both microgeographic

evaluations of Vietnamese populations of widely distributed species (she's a veteran of four tours), taking the driver's seat in describing several new species of Vietnamese megophryids, as well as investigating higher taxonomic phylogenies. Broad-based, she uses both molecular and morphological data equally. She'll be done in '99. M.Sc. student Raoul Bain has now fully recovered from his "most interesting bout of malaria"—he's a three-time veteran of Vietnam field work. Raoul (alias Rommy II), is writing-up his morphological and molecular evaluations of the large, odoriferous ranids of Vietnam, and has substantial documentation that some "species" are actually quite large species complexes. Doctoral student Tanya Trépanier started in 1997 and is looking at the evolution of fringe-toed lizards (*Uma*) in excruciatingly great detail, SSCPs and all, and on an international basis. Her "preliminary" molecular data—only 2000 bp thus far from 20+ populations—are very exciting. She will follow her Ph.D. in biology with a law degree, only to become involved in international conservation law and policy-making. Michéle Bobyn was close to finishing her Ph.D. unscrambling the phylogeny of *Cnemidophorus* when she decided to take employment as a forensics specialist with the Province of Ontario's Centre for Forensic Sciences—something useful for society, but then, Canadians are like that, eh! Dr. Leslie Lowcock is back in town and he's threatening to continue his work on the damage to the anuran genome by pesticides and fertilizers. Finally, undergraduate student projects range from evaluating Vietnamese frog voices to DNA sequencing studies.

Elsewhere in the ROM, recent paleontological research (which does have some relevance to extant species) in the laboratory of Prof. Hans-Dieter Sues focuses on changing diapers, dinosaurs, and therapsids, and includes cladistic investigations of rhynchocephalians, diaper tabs, and crocodilians. Hans' field work concentrates in eastern North America and Central Asia. And Prof. Chris McGowan continues to actively publish on ichthyosaurs—like it will ever end. His recently graduated student, Ryosuke Montani, has prepared the first "proper" phylogenetic evaluation of the group.

As well, there is no shortage of herpetologically-oriented work at the University of Toronto. Check out the U. of T. Zoology web site and look up Prof. Robert Reisz (paleontologist), Prof. Rick Ellinson (developmental biologist), Prof. Richard Liversage (regeneration), Prof. Nick Mrosovsky (bio-rhythms), Prof. Dan Brooks (parasites), and Prof. Sherwin Desser (parasites).

Amphibian Species Diversity Exceeds that of Mammals

FRANK GLAW
Zoologische Staatssammiung München
Münchhausenstr. 21, D-81247 München, Germany

and
JÖRN KÖHLER
Zoologisches Forschungsinstitut und Museum Alexander Koenig
Adenauerallee 160, D-53113 Bonn, Germany
e-mail: uzs13b@uni-bonn.de

Since the official beginning of zoological nomenclature by Linné in 1758, the number of known mammals has always been higher than that of amphibians. Wilson and Reeder (1993) recognized 4629 mammal species, while their number was estimated to be about 4675 in the middle of 1995 (Hutterer 1995). These estimates prompted us to check the current number of valid amphibian species and their description rates to compare them with those of mammals.

To estimate the current number of living valid amphibian species we compiled a synthesis of the data provided in *Amphibian Species of the World* (Frost 1985) and the additions and corrections to this work by Duellman (1993). The *Zoological Record* (1990–1995) was used as the main data source to complete this synthesis. Additionally, we searched recent herpetological and zoological journals for taxonomic changes (descriptions of new species, resurrections from synonymy, and new synonyms). All these data (available at www.mabnetamericas.org) were processed on IBM compatible computers using Microsoft Access and Excel software. Calculations about expected future discovery rates of amphibian species were based on a linear regression of the description rates between 1964 and 1994. Our taxonomic classification follows Duellman (1993). The data on mammal species richness were taken from Wilson and Reeder (1993) as updated by Hutterer (1995).

Annual rates of amphibian species descriptions have been extremely variable (Fig. 1). Most of the outstanding peaks are due to important contributions of single scientists (1758: Linné; 1768: Laurenti; 1799: Schneider; 1803: Daudin; 1824: Spix; 1841: Duméril and Bibron; 1859: Günther; 1882: Boulenger; 1968: Taylor). Despite this variability, increasing rates of description are evident. This trend becomes obvious when the rates are clustered in decades (Fig. 2). Comparison of Fig. 2 with the graph provided by Wilson and Reeder (1993) demonstrates that the largest burst of species discoveries in mammals is over (see also Morell 1996), whereas description rates in amphibians are still increasing. Decrease of description rates between 1910 and 1919 as well as between 1940 and 1949 possibly are due to the first and second world wars, respectively.

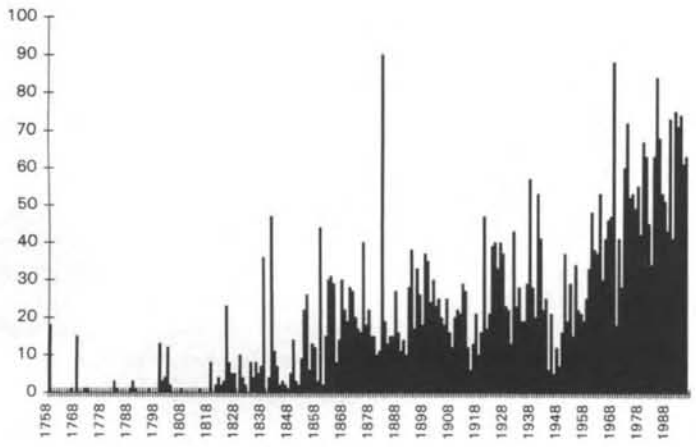

FIG. 1. Annual amphibian species descriptions since 1758 (synonyms not included).

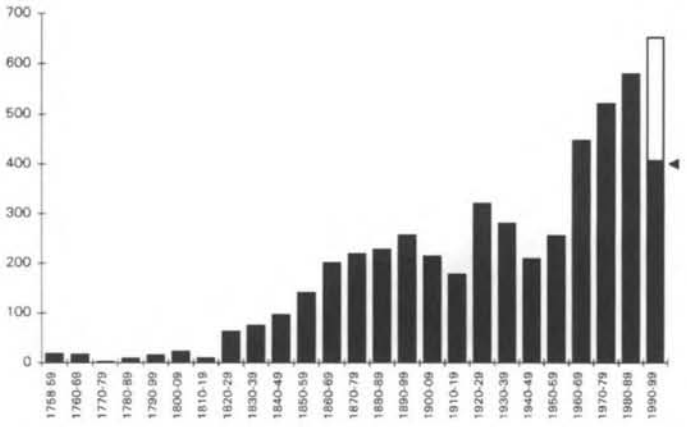

FIG. 2. Amphibian species descriptions since 1758 clustered in decades (synonyms not included). Arrow indicates end of 1995. Species descriptions until the end of this century are extrapolated.

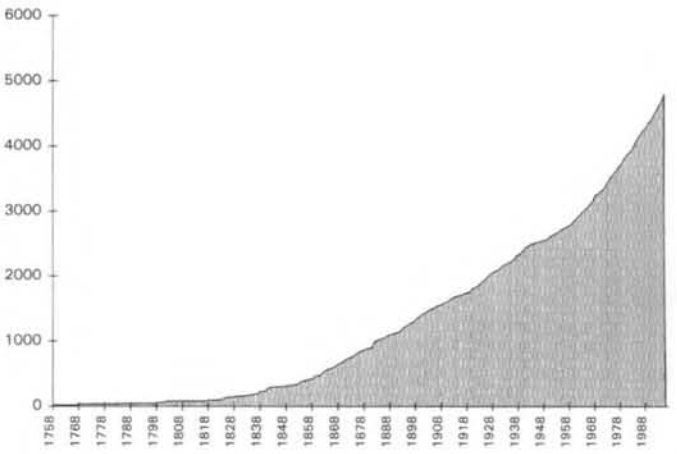

FIG. 3. Increase of valid recognized amphibian species from 1758 to 1995.

The cumulative analysis (Fig. 3) revealed that the number of recognized species strongly increases. The total number of valid amphibian species at the end of 1995 was at least 4780 (Anura: 4204, Urodela: 411, Gymnophiona: 165). Species richness of the ten largest anuran families at the end of 1995 was as follows: Leptodactylidae (906; among them 544 species in the genus *Eleutherodactylus*), Hylidae (754), Ranidae (711), Bufonidae (400), Microhylidae (316), Hyperoliidae (230), Rhacophoridae (228), Dendrobatidae (180), Centrolenidae (116), and Myobatrachidae (116). The largest family of the order Urodela is the Plethodontidae (263 species). The biogeographical portions

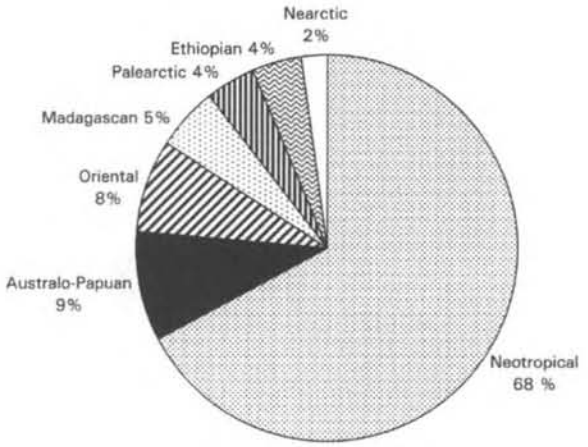

FIG. 4. Percentages of amphibian species described from the beginning of 1986 through the end of 1995 in different biogeographical regions.

of species descriptions during the last ten years are shown in Fig. 4. A comparison with the total number of mammal species showed that since 1994 amphibian species diversity exceeded that of mammals when both vertebrate classes had around 4650 species.

For comparison of species numbers several factors must be taken into account, e.g., subjective opinions and different species concepts of taxonomists, completeness of taxonomic inventories, percentage of synonyms, access of characters and methods. However, we consider these factors to be of similar significance in amphibians and mammals. Our comparison of species discovery rates suggests that the actual number of amphibian species is much higher than that of mammals. If we assume a continuous linear increase of species numbers in amphibians we will have reached 5000 species at the end of this century. The increasing use of modern techniques, especially the analysis of advertisement calls in anurans as well as biochemical and genetic studies, undoubtedly will lead to the discovery of many new species in the future. Recent field surveys in tropical rainforest areas (e.g., Madagascar and Bolivia) indicate that this trend seems realistic for at least the next two or three decades. These estimates demonstrate the urgent need for well-managed national and international biodiversity research programs for amphibians.

Acknowledgments.—We thank Wolfgang Böhme, Darrel R. Frost, and Robert F. Inger for comments on the manuscript.

Does *Batrachoseps* Occur in Alaska?

DAVID B. WAKE
ELIZABETH L. JOCKUSCH
and
THEODORE J. PAPENFUSS
Museum of Vertebrate Zoology, University of California
Berkeley, California 94720-3160, USA

Present address of ELJ: Department of Molecular and Cellullar Biology, University of Arizona, Tucson, Arizona 85721, USA

The Alaska worm salamander, *Batrachoseps caudatus* Cope, 1889, was collected only once, in 1882, on Annette Island, one of the southernmost islands in Alaska (Cope 1889). The species is known from a single specimen (USNM 13561) preserved in the National Museum of Natural History, Washington, D.C. The specimen was sent to the Museum by Lt. H. E. Nichols, in command of the ship "Hassler," which worked in Alaskan waters in 1882. The specimen, supposedly collected at Hassler Harbor on Annette Island, was catalogued into the collections of the National Museum of Natural History along with other specimens of species known to occur in southeastern Alaska, but also with specimens that occur in the vicinity of Mare Island, near San Francisco, California (we are grateful to R. Crombie for providing archival information). A morphologically similar species, the California slender salamander, *Batrachoseps attenuatus* (Eschscholtz 1833), occurs in the vicinity of Mare Island, and a California animal may have been mixed with Alaskan material. The species may not exist in Alaska at all (Wake 1993). However, Lt. Nichols was known to have been careful and precise, and perhaps there has been an inadequate search in this area (Hendrickson 1954; Hodge 1976). While it would seem unlikely that an amphibian species would be endemic in Alaska, recent discoveries have led to suggestions that there may have been Pleistocene refuges, or even an ice-free corridor along the North Gulf Coast of present-day southeastern Alaska (MacDonald and Cook 1997). Accordingly, we decided to make a careful search for these salamanders. Such activity seemed appropriate, given the rapid changes taking place in southeastern Alaska due to forest harvest and other human activities. If there is an endemic salamander in Alaska, care should be taken to make certain that it survives.

Through the courtesy of Jim and Pat Beal of Metlakatla, Alaska, we were able to visit a number of sites on Annette Island between August 4 and August 10, 1996. We failed to find any *Batrachoseps*, although in our collective judgement the environmental conditions for such an occurrence were favorable.

Annette Island consists of two distinct parts. There is a low southeastern peninsula that is the population center for the island, including the village of Metlakatla, a now largely abandoned army camp and large airport, a fish hatchery, dump, radio towers, fish cannery, and boat harbor. The population of the island is something less than 2000 people, all of whom live on this peninsula. The peninsula is relatively flat, with one 150 m hill and many inlets, bogs, and ponds. The remainder of the island is high, rocky, and rough, with a number of old logging roads. The highest point on the island is 1094 m. Rock, most of it Paleozoic (mainly Silurian), dominates the main part of the island; in the north and east portions of the main island upper Triassic and middle to upper Jurassic rocks are exposed (Berg 1972). The youngest rocks on the island are Cretaceous, dated at 87 myr, and these are extremely limited in extent. There is a rich and dense fringing forest around the entire island, sometimes extending well inland. However, the forest is usually not more than a few hundred meters wide, and

often narrower than that. Then the forest breaks up into muskeg in the interior and at higher elevation.

We traveled by boat, stopping at various places and going ashore in a Zodiac. We made brief stops in several areas, but four sites deserve special mention:

1. Hassler Harbor (55°07.75'N, 131°35.00'W), northeast side of Annette Island, between Nedzaheen Cove and Harbor Point. This was our main destination and we spent the largest amount of time here, visiting the area twice. The Harbor itself is small but well protected, and it is easy to see why it was an anchorage for the "Hassler" (which is known to have been here on August 10, 1882; Hodge 1976). It is protected by the very small but forested Pow Island. The forest fringing Annette Island near the Harbor is narrow, but the habitat appears suitable for plethodontid salamanders. The understory vegetation is dense and diverse, and several species of huckleberries (*Vaccinium* spp.) were especially abundant. There is abundant downed timber, some of it well rotted, and loose rocks were abundant along creeks and where the creeks cut through underlying rock, which in this region is upper Triassic and middle to upper Jurassic (Berg 1972). We also worked small talus zones, although they are not abundant in the forested zone where we concentrated our work. The soil was moist and seemingly ideal for salamanders, and temperatures in the shade at mid-day on sunny days reached 21°C.

2. Crab Bay region (55°07'N, 131°22'W), east side of Annette Island. This was among the most favorable habitats we investigated. We spent a full day here. Large cedar, spruce, and hemlock trees occur on a relatively flat base with abundant cover, appropriate for plethodontids. Metamorphosed limestone outcrops are found (upper Triassic in age, Berg 1972), and there are several small caves. We investigated a wide range of habitats, including creek margins and caves. Many of the invertebrate associates of plethodontid salamanders found in Washington, Oregon, and California were present, including snails, slugs, snail-eating beetles, millipedes, and earthworms. We found newts (*Taricha granulosa*) in the creek, and one under a piece of bark.

3. Peninsula north of Annette Bay near landing (55°15.2'N, 131°31.3'W), extreme northwest Annette Island. This was excellent habitat, with some fine forest, notable for the size of the yew trees. The trees were especially large and understory vegetation was dense on the slopes along the north shore of the Bay. However, we did not penetrate very far into the woods (ca. 200 m) before we encountered rock (the entire peninsula is middle or upper Jurassic in age [Berg 1972]) and muskeg. Newts were common in this area.

4. Tamgas Harbor, along the east side on main part of Annette Island, just above Creek Point. This is near the fish hatchery. The forest in this protected area is excellent—large spruce, hemlock, and cedar trees. This is near the southern end of the island, and rocks in the area are all Silurian or older in age (Berg 1972). The habitat appears to be ideal for salamanders, but we found none.

5. Metlakatla Peninsula. This area is highly disturbed by all kinds of activities, especially those associated with the now nearly abandoned airport. There are numerous ponds, and at night we found toads (*Bufo boreas*) to be relatively common on the roads. We did not spend much time in this area because it did not look appropriate for plethodontid salamanders.

Abundant habitat exists on Annette Island for plethodontid salamanders, and many of the animal and plant associates of plethodontids further to the south are found here. For Alaska, the climate is mild, and plethodontids should be able to survive the winters easily. We found two species of amphibians, and local residents described a third, possibly *Ambystoma gracile* or *A. macrodactylum*. However, no one, including good amateur naturalists with whom we spoke, described a salamander that might have been a plethodontid. They were familiar with newts and toads, however.

We are not certain that the "Hassler" spent more than a single day anchored at Hassler Harbor. If it really was as short a time as a day, it seems unlikely that three experienced salamander collectors working under ideal conditions at the same time of the year for five days would fail to find the species. However, we did fail to find one species that local residents described to us, and of course it is risky to make positive statements on negative evidence under any circumstances.

Plethodontid salamanders probably do not occur in Alaska, although they might come relatively close. However, these are not members of the genus *Batrachoseps*, but rather of *Ensatina*. There are no authenticated records for salamanders of the genus *Batrachoseps* north of the Columbia River. Furthermore, the absence of Cenozoic rocks on Annette Island suggests that more recent strata were ground off by Pleistocene glaciers. If so, it is likely that there was no Pleistocene refugium on Annette Island. The limestone outcrops generally are highly degraded and the little exposed limestone that contains caves does not have sufficiently large caves to have formed long-term refuges. It seems unlikely that plethodontid salamanders would have survived the Pleistocene glaciation on this island. The toads and newts have most likely arrived recently. Allozymes and mitochondrial DNA sequences of Alaskan newts are very similar to those from populations from the state of Washington (Tan 1994); this suggests that the newts made it to Alaska after the glaciers receded.

Some parts of southeastern Alaska may have escaped Pleistocene glaciation, and it may be that the specimen in the National Museum of Natural History came from one of these areas and was mislabeled. However, if we admit to the possibility of mislabeling, it seems most likely that the salamander came from the vicinity of the California port of the "Hassler," Mare Island, near Vallejo, Solano County, California. The species *Batrachoseps attenuatus* is common in the Vallejo area, and the holotype of *Batrachoseps caudatus* (which has been examined by DBW) cannot be distinguished from large members of that species.

In summary, we found no plethodontid salamanders on Annette Island, although conditions appeared to be favorable. Given the good conditions and the favorable environment, the fact that three experienced collectors failed to find any *Batrachoseps* seems significant. The geological evidence together with the great geographic separation from other *Batrachoseps* makes it unlikely that the genus occurred on Annette Island in 1882, and the virtual identity of the specimen to members of *Batrachoseps attenuatus* suggests that the holotype is a mislabeled specimen of that species. We conclude by concurring with other authors (e.g., Schmidt 1953) that *Batrachoseps caudatus* Cope, 1889, should be considered a subjective junior synonym of *Batrachoseps attenuatus* (Eschscholtz, 1833).

Acknowledgments.—We thank Jim Beal for use of his boats, for expert guidance, and general assistance. Our work was supported by U.S. Forest Service Cooperative Agreement PNW 94-0618.

Rare Nesting Occurrence of the Leatherback Sea Turtle, *Dermochelys coriacea*, in Northwest Florida, USA

TERESA J. CALLESON
GEORGE O. BAILEY

e-mail (TJC): calleson@digitalexp.com

In the continental United States, Florida is the only state to consistently document nesting of the leatherback sea turtle, *Dermochelys coriacea*, although nesting has been reported from Texas to Georgia (Ernst et al. 1994; Ruckdeschel et al. 1982). From 1979–1992, as many as 188 leatherback nesting emergences were documented in a given year, with 50.1% of all such events occurring in Palm Beach County in southeast Florida (Meylan et al. 1995). In northwest Florida, observations of leatherbacks have been noted for the mouth of the Ochlockonee River near Panacea and St. Andrew Bay near Panama City (Yerger 1965). Aerial surveys conducted by the National Marine Fisheries Service in 1987 and 1993 produced 13 sightings in northwest Florida, including three solitary leatherback sightings in the waters off Dog Island in Franklin County and two additional sightings near Cape San Blas in Gulf County in 1993 (K. Mitchell, pers. comm.). Although numerous leatherback sightings have been recorded for this region, few nesting events are revealed in historical accounts.

A single leatherback nest was confirmed between Phillips Inlet and Destin in September 1962 when hatchlings were discovered on the beach (Yerger 1965). St. Vincent National Wildlife Refuge in Franklin County was the site of an additional leatherback nesting event in 1974 (LeBuff 1990; Meylan et al. 1995). Nearby St. Joseph Peninsula State Park in Gulf County also documented three emergences, including two nests and a false crawl, more recently in 1993 (Meylan et al. 1995; J. Mitchell, pers. comm.). The first documented nesting event in the park occurred on 31 May 1993, and later nest excavation revealed the presence of 110 eggs, including 86 yolked eggs (J. Mitchell, pers. comm.).

In 1995, four leatherback emergences (Fig. 1) were documented in Franklin County, resulting in three nests with verified eggs and a false crawl. The first documented nesting event occurred on 5 May 1995, and the final emergence was documented on 10 June 1995. Since leatherbacks generally average 5–7 nests per season (NMFS and USFWS, 1992) with only about 16–31 individuals of the species nesting in Florida each year (Meylan et al. 1995), these 1995 accounts may be attributed to multiple emergences by the same nesting female.

The location of each nesting event was obtained with the use of a hand-held Loran-C unit. All four emergences occurred on St. George Island with the second nest located within St. George Island State Park boundaries. The distance between consecutive nesting attempts varied from 0.8 to 13.7 km, with an average distance of 8.4 km between successive emergences. Northwest Florida was impacted by three hurricanes during the 1995 nesting season, and the final nest was not relocated to evaluate hatching success after Hurricane Erin in August.

In early August, the first leatherback nest was evaluated and was found to include 127 unhatched eggs including 85 large, yolked eggs and 42 smaller, yolkless eggs. The presence of smaller, yolkless eggs is common for this species, although their exact function has yet to be determined (Leslie et al. 1996; Rostal et al. 1996). Ultrasonography has revealed that these are the last eggs produced in the oviduct (Rostal et al. 1996). Close examination of this clutch revealed that the eggs also lacked the presence of white spots or visible embryos, and thus were probably infertile since white spot development between the vitelline membrane and the shell membrane is generally considered an indicator of fertile eggs (Whitmore and Dutton 1985).

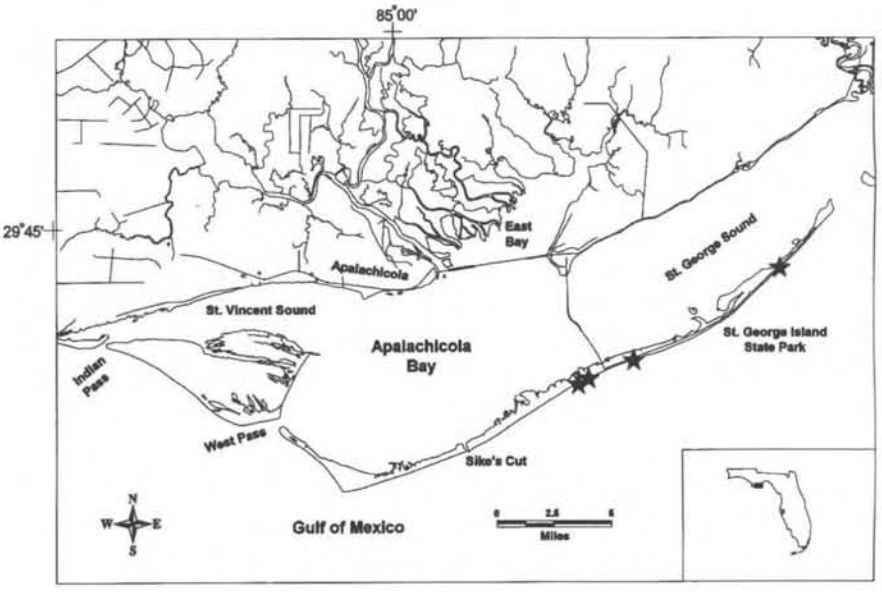

FIG. 1. Leatherback emergence locations in Franklin County, Florida, during the 1995 nesting season.

Staff from the St. George Island State Park examined the second nest for hatching success in mid-August. This clutch, comprised of 139 unhatched eggs of similar size ranges as the first documented clutch, included 96 yolked eggs (Ogles, pers. comm.). Once again, no eggs appeared to contain embryos. These clutch sizes, although representing only two samples, appear consistent with previous studies which exclude smaller, yolkless eggs from clutch size estimates (Hirth and Ogren 1987; Leslie et al. 1996). Hirth and Ogren (1987) found leatherbacks to lay an average clutch of 81.57 eggs on beaches near Laguna Jalova, Costa Rica.

Poor nest site selection, infertility, embryonic mortality, poaching, predation, and root development have been recognized in the past as reasons for reduced hatching success for leatherback and green sea turtles, *Chelonia mydas* (Leslie et al. 1996; Whitmore and Dutton 1985). Due to the few historical records of leatherbacks in northwest Florida and the characteristics of these two clutches, evidence seems to suggest infertility as the reason for lack of embryonic development and hatching success. The panhandle region of Florida, especially Franklin County, is relatively undeveloped in comparison to other regions of the state. Certainly the possibility exists that leatherback females nested on remote beaches in the past, thus escaping human detection. Further monitoring of local nesting beaches in years to come may provide additional knowledge concerning the nesting density of the leatherback sea turtle and a better estimate of the number of nesting females in northwest Florida.

Acknowledgments.—We thank Thom Lewis of the U. S. Fish and Wildlife Service and Roy Ogles and Bruce Drye of the St. George Island State Park for their time and support in monitoring sea turtle nesting in Franklin County and, in particular, the leatherback nests of 1995. We also extend our appreciation to Joe Mitchell of the St. Joseph Peninsula State Park for contributing information from past leatherback nesting events on Gulf County beaches and to Karen Mitchell of the National Marine Fisheries Service, Pascagoula, Mississippi, for providing leatherback sighting locations for the Florida panhandle.

Scolecophidian Arboreality Revisited

INDRANEIL DAS*
and
V. WALLACH
Museum of Comparative Zoology, Harvard University
26 Oxford Street, Cambridge, Massachusetts 02138, USA
e-mail (VW): vwallach@oeb.harvard.edu

**Present address: Centre for Herpetology, Madras Crocodile Bank Trust*
Post Bag 4, Mamallapuram, Tamil Nadu 603 104, India

Arboreality in scolecophidians was reviewed recently by Gaulke (1995). We compile here records that are hitherto unpublished as well as reports that were omitted in Gaulke's review on arboreality in the Typhlopidae and Leptotyphlopidae.

On 8 March 1994, an adult *Ramphotyphlops braminus* (ZSI 25115) was found under peeling bark, ca. 1.5 m vertically above substrate and ca. 5 m up along a reclining termite-infested dead coconut tree (*Cocos nucifera*) on Car Nicobar (09°10'N; 92°47'E), Bay of Bengal, India. The animal presumably was feeding on worker termites, among which it was found. Data associated with the following museum specimens provide additional evidence for arboreality among scoledophidians: one *Leptotyphlops tenellus* (USNM 286953) from a palm tree in St. George, Trinidad, and another (USNM-field no. 175504), collected from under bark of a tree more than 1 m off ground; *Ramphotyphlops angusticeps* (FMNH 41968), 4 m up in a palm tree, Guadalcanal, Solomon Islands; and *R. depressus* (USNM 121256), found climbing a tree, Manus Island, Bismarck Archipelago, Papua New Guinea (fide letter 170465 by Emil Bogen to the USNM).

There are several other anecdotal literature records of arboreality in scolecophidians that were cited by Gaulke (1995), including *R. angusticeps* at night in fronds of a small palm tree about 4 m above the ground, Guadalcanal, Solomon Islands (McCoy 1980); five *R. suluensis* from 2–3 m in height in a tree at night, Sulu Archipelago, the Philippines (Gaulke 1995, 1996); *R. nigrescens* 5 m up on a she-oak tree (*Casuarina* sp.), Australia (Shine and Webb 1990); and *L. dulcis* 1 m up in a sycamore tree (*Platanus occidentalis*), Waco, Texas, USA (Plsek *fide* Gehlbach in Vanzolini 1970).

Additional literature records suggesting arboreal activity include one *Leptotyphlops albifrons* ca. 0.5 m up the rough bark of a half dead tree, another coiled around a live bamboo twig in daytime close to the ground, Guyana (Beebe 1946), and a third under the bark of a tree (Mole 1924); *L. dulcis* in nest of screech owl (*Otus asio*), Texas, USA (Gehlbach and Baldridge 1987); *L. macrolepis* ca. 0.6 m up a vertical concrete wall, Colombia (Dunn 1944); *L. macrorhynchus* from thatched roof of a house, Pakistan (Minton 1966); *L. tenellus* ca. 2 m up a tree trunk, Brazil (Vanzolini 1970); *L. tesselatus* in the wall of an old adobe house in Lima, Peru (Schmidt and Walker 1943); *Ramphotyphlops australis* from a dead standing blackboy [burnt yacca grass tree], *Xanthorrhoea* sp., in a dry swamp, Australia (Chapman and Dell 1975); one *R. braminus* ca. 2 m up on a dead mango tree, *Mangifera indica*, Australia (Swanson 1981), and one in an insect hole within a piece of sugarcane (*Sachharum officinalis*) a considerable height above the ground (Annandale 1906); *R. cumingii* from the trunk of a tree that had bored ant tunnels beneath the bark and multiple specimens from root masses of aerial ferns, including the giant tree fern (*Asplenium nidus*), high in forest trees (Taylor 1919, 1922); *Typhlops richardii* 1.5 m up on a papayo tree (*Metopium toxiferum*), Puerto Rico (Tolson and Campbell 1989); and *T. arenarius* 1.5 m up on a large tree, Madagascar (Glaw and Vences 1994). Edgar and Lilley (1993) characterized *R. olivaceus* from

Seram, Maluku, eastern Indonesia, as being arboreal and fossorial. Data associated with their unregistered material in the BMNH provide further support: one specimen (S143) from an epiphyte at 2.2 m; one (S198) 2.5 m up tree on vine; one (S211) 2 m up tree climbing in vines; one (S250) 2.5 m up ant nest in leaf; one (S271) 2 m up in tree; and one (S270) 2.5 m up in vine.

For whatever reason (expanding range, foraging for food, and/or following pheromone trails of conspecifics of the opposite sex), the above reports make it clear that arboreality is, at the least, an occasional occurrence in scolecophidians. It may be a common activity and some species may be more abundant in trees than underground. We suggest that collectors also look up, as well as down, in the future.

Acknowledgments.—We thank A. Wynn and R. I. Crombie (USNM) and A. Resetar (FMNH) for facilities in their respective collections, D. T. Iskander and C. J. McCarthy for drawing our attention to the unregistered BMNH material from Seram, and J. Daltry and A. Wynn for comments. The Centre for Herpetology and the Royal Netherlands Embassy supported field work in the Nicobars. Additional support came from a Fulbright Fellowship to the first author.

TECHNIQUES

Sodium Brevital as an Anesthetizing Agent for Crotalines

LYNDA R. MILLER
and
WILLIAM H. N. GUTZKE
Ecological Research Center, Department of Biology
University of Memphis, Memphis, Tennessee 38152, USA
e-mail (LRM): LRMILLER@MSUVX2.MEMPHIS.EDU

Many different methods of anesthetizing reptiles exist. Two such methods are cold narcosis, which involves cooling the animal to just above freezing, or the use of an anesthetic gas such as halothane, that is inhaled by the animal. When working in a potentially harmful situation such as the mouth of a pit viper, these methods may not be acceptable means of anesthetizing the animal. Cold animals are still capable of striking and could prove a danger when working in close proximity to the fangs. Apparatus associated with using a gas anesthetizing agent interferes with any work being done in the mouth region. The presence of a trachea tube is necessary to maintain a sufficient level of anesthetization, thus limiting work space and manueverability when working in the oral area. Injection of sodium brevital, a barbituate, proves useful when gas and cooling are not convenient methods. Dosages of 15 mg of sodium brevital per kilogram body weight have previously been reported (Wang et al. 1977). This is successful with many species of lizards and snakes. However, venomous snakes of the subfamily Crotalinae are unable to withstand this dosage. This may be attributed to the reduced musculature in comparison with colubrids. We have found that one-third of the published dosage of 15 mg/kg of body weight (i.e., 5 mg/kg) injected approximately mid-way between the cloaca and the end of the tail will anesthetize crotalines sufficiently for procedures involving the vomeronasal duct which is located in close proximity to the fangs (Miller and Gutzke, in press). Pregnant individuals and neonates tolerate only one sixth of the published dose (i.e., 2.5 mg/kg body weight).

In our study, 18 animals were anesthetized with sodium brevital. Species included were *Agkistrodon piscivorus, A. contortrix, Crotalus horridus, C. atrox, C. lepidus, C. mitchelli, C. viridis*, and *Sistrurus miliarius*. Animals ranged in size from approximately 4 g for neonate *A. piscivorus* up to 1500 g in the large adult crotalines. Induction of anesthetization occured within 30 min of injection. The soporific state was maintained for 1–1.5 h while the surgery was performed. All anesthetic and surgical events occured at room temperature, approximately 22–23°C. Recovery time varied from 10–24 h with full recovery within 48 h. The snakes were maintained in the laboratory long term (in excess of one year) after the anesthetization procedure and no adverse affects due to the sodium brevital were observed.

Reptile Sheds Yield High Quality DNA

ANNMARIE CLARK
BEECS Genetics Analysis Core, University of Florida
Box 110700, Gainesville, Florida 32611-0700, USA
e-mail: aclark@icbr.ifas.ufl.edu

Venomous, small, or endangered reptiles may pose special problems in securing tissue samples for genetic analysis. Obtaining blood from venomous reptiles requires specialized training. The difficulty and danger of this approach, especially for inexperienced handlers, is apparent. Collection of tissue samples from very small individuals (e.g., *Tantilla*) may be difficult without sacrificing the animal. Benefits of non-invasive sampling apply to all collections of tissue from live animals, but are especially compelling when rare or endangered taxa are involved.

In an earlier report, Bricker et al. (1996) describe methodology to obtain high molecular weight DNA from shed snake skins. While effective, this method requires special training and safety equipment. Optimally, DNA extraction procedures should be safe for personnel with modest lab experience, require minimal handling of toxic materials, and have minimal disposal costs, yet still reliably produce high quality DNA. Several different DNA extraction methods were considered as protocols for shed snake skins (e.g., Ausubel et al. 1995, Bricker et al. 1996, Hillis et al. 1996). Those requiring large volumes of biohazardous reagents were rejected due to the expense of waste disposal. Methods using guanidine thyocyanate (Bricker et al. 1996) were also ruled out due to the possible generation of toxic hydrogen cyanide gas. The favored approach was a modification of a protocol using CTAB (hexadecyltrimethylammonium bromide) and proteinase K.

To assess the durability of DNA available for extraction, robustness of the protocol, and its effectiveness across species, sheds were obtained from a variety of conditions. Here I report the results of DNA isolations from shed skins for 11 species of snakes and 2 species of lizards. Fourteen snake sheds (*Crotalus)* were collected in the field, where they had been exposed to weathering conditions for undetermined periods. Other sheds were collected from captive animals and were in optimal condition when received for isolations. Colleagues who provided samples were asked to allow sheds to air dry thoroughly before shipping them to our laboratory.

Sheds were collected from neonates, hatchlings, or adults of *Crotalus horridus* (N = 19), *C. adamanteus* (N = 1), *C. enyo* (N = 1), *C. lepidus klauberi* (N = 1), *C. mitchellii* (N = 1), *C. triseriatus armstrongi* (N = 1), *C. unicolor* (N = 2), *C. willardi* (N = 1), *Pituophis melanoleucus* (N = 2), *Pituophis catenifer* (N = 1), *Tantilla relicta* (N = 1), *Ophisaurus apodus* (N = 1), and *Iguana iguana* (N = 1). All sheds are stored at room temperature in separate paper envelopes or loose plastic sample bags.

A 1-inch square piece of shed (approximately 0.02 g), preferably from the dorsal surface, is cut into small pieces and placed into a sterile 1.5 ml Eppendorf tube. Scissors used to process the sheds are cleaned thoroughly, dipped in ethanol, and flamed between specimens to prevent cross contamination. Gloves are used and the work area is thoroughly cleaned with ethanol between samples. Each sample is treated with 700 ul of CTAB extraction buffer (100 ml 1M Tris-HCl, pH 8.0, 280 ml 5M NaCl, 40 ml 0.5M EDTA, pH 8.0, 20 g CTAB, 2 ml 2-mercaptoethanol, dH_2O to 1 liter [Ausubel et al. 1995]) and 5 ul proteinase K (20 mg/ml in 50% glycerol). The mixture is shaken on a mechanical vortex for about 5 s and incubated at 50°C overnight. Samples placed in a 65°C water bath for 2–4 h also gave good yields.

After removal from the water bath, tubes are shaken again before addition of 700 ul buffered phenol. This mixture is shaken briefly and placed on a rocking platform for 5 min and subsequently centrifuged at 12,000 rpm for 5 min. Generally the supernatant in phenol extractions is the aqueous phase containing the DNA. However, due to an inversion, the supernatant in this first extraction step is phenol; the aqueous phase with DNA is at the bottom of the tube with the debris from the shed. This inversion was observed in all 33 extractions. The top layer is drawn off with a pasteur pipette and set aside in a sterile 1.5 ml Eppendorf tube. The bottom layer is drawn off with a new pipette by pushing aside the debris and drawing up as much of the liquid as possible. This aqueous phase is transferred to another sterile 1.5 ml Eppendorf tube. Again, 700 ul phenol are added, the mixture is shaken, incubated on a rocker for 5 min, and centrifuged as before. After centrifuging, the supernatant is drawn off and placed into another sterile 1.5 ml Eppendorf tube. (If a separation of layers does not occur, the previous step is repeated with the top layer from the first step.) Two extractions, each using 700 ul phenol:chloro-form:isoamyl alcohol (25:24:1) and the supernatant from the previous step, are done by shaking the mixture, incubating for 5 min on a rocker, centrifuging for 5 min as above, and drawing off the supernatant into sterile tubes. Two additional extractions, each using 700 ul chloroform:isoamyl alcohol (24:1) and the supernatant from the previous step, are sufficient to remove residual phenol.

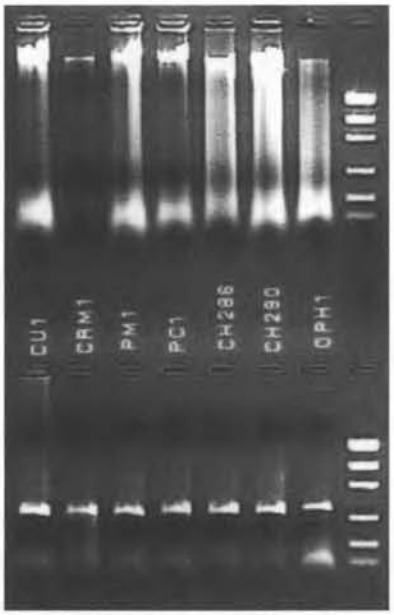

FIG 1. Representative sampling of DNA isolations (top of gel) using this protocol and the resulting PCR amplifications (bottom of gel) using cytochrome *b* primers corresponding to H15149 (Kocher et al. 1989) and L14725 (Meyer 1993). Lanes 1 through 8 from left to right are 1: *Crotalus unicolor*, 2: *C. mitchellii*, 3: *Pituophis melanoleucus*, 4: *P. catenifer*, 5: *C. horridus*, 6: *C. horridus*, 7: *Ophisaurus apodus*, and 8: low mass DNA ladder.

In a new tube, the supernatant is combined with 50 ul 3M sodium acetate and 2.5 volumes of ice cold 95% ethanol, shaken or mixed, and stored at -20°C overnight. The tubes are then centrifuged at 12,000 rpm for 10 min, and the ethanol is removed by careful pipetting, so as not to dislodge the DNA pellet. The pellet is washed by adding 1 ml 70% ethanol and centrifuged for 10 min. The ethanol is carefully removed as above, and the pellet is dried, preferably in a speed-vac, although this can also be accomplished by inverting the tubes at room temperature for 2–4 h or

until the ethanol has evaporated completely. The DNA pellet is resuspended in 200 ul TE buffer (10 mM Tris-HCl, 1 mM EDTA, pH 8 [Ausubel et al. 1995]).

This method of extracting DNA from sheds is relatively safe and can be easily taught to students with limited lab experience. A small amount of shed skin (0.02g) yielded 0.79–19.7 ug/ml DNA, which is sufficient for such molecular procedures as PCR, RFLP analysis, microsatellite screening, etc. All but one sample yielded ample amounts of high quality DNA and consistently produced a PCR product (Fig. 1). The sample that did not produce PCR products was damp, odiferous, and in poor condition when received. Of the 33 sheds processed using this protocol, 10 have been sequenced and used in data analysis. This method of DNA extraction probably is applicable to all species of reptiles that shed, thereby greatly facilitating the collection of samples from venomous, small, or rare reptiles as well as those in zoo collections.

Acknowledgments.—I thank B. W. Bowen for his encouragement and the Biotechnology Program at UF for providing the lab space to perfect this protocol. My thanks also go to F. Kraus for generously sharing a prototype protocol and to P. E. Moler, W. H. Martin, M. J. Russell, R. Harrington, A. J. Hendershott, A. L. Braswell, T. Johnson, G. McLaughlin, and R. Bartlett for providing the sheds of the various species of *Crotalus*. Special thanks to A. L. "Sam" Bass for her support and patience.

We have adapted the method of Hay et al. (1994) to make an agar-based food source for anuran larvae that can be used in studies of growth and development. Currently we are using this technique to study the impact of the potential defense chemicals found in algae and other periphyton on the growth and development of ranid larvae. Our basic food source is the widely used 3:1 mix of ground rabbit chow and TetraMin fish flake (e.g., Britson and Kissell 1996). Once ground, the mixture is passed through a fine sieve to promote a uniform particle size. For every 4 g of base food, 0.75 g of agar is brought to a boil in 30 ml of distilled water. Another 30 ml of cold distilled water is added to the 4-g base. The two solutions are then mixed together, put in a mold (Fig. 1), and allowed to solidify for at least 10 min. For our study of plant defensive compounds, the base food is evenly coated with the compound by first dissolving a known amount of the substance in an appropriate solvent. This solution is then mixed with the dry base food in a Rotavapor (Büchi Instruments) until the solvent has evaporated. When only small amounts of solvent are necessary, we omit the evaporation procedure. Once the food has been coated with the chemical, water is added and the procedure is followed as outlined above. Once the entire mixture has been allowed to solidify, we imprint it with a surface grid and cut food squares of the desired size.

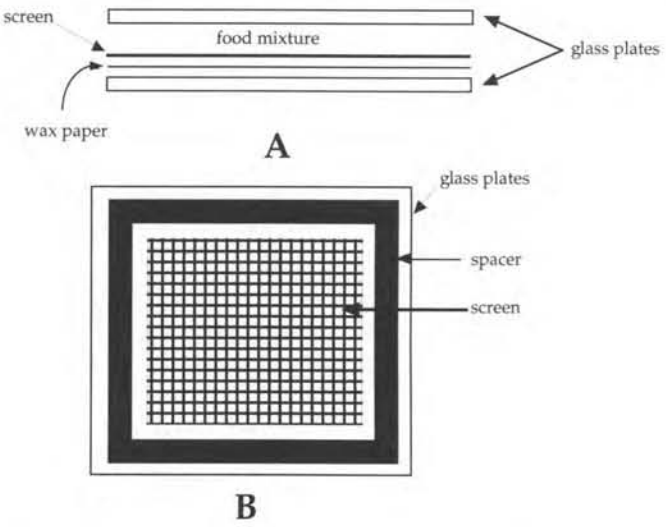

FIG. 1. Examples of molds used to construct tadpole foods. (A) Simple mold for obtaining a very thin and uniform coating of food on the screen base. (B) Top view of a mold type used to make foods of greater thickness. The diameter of the spacer controls food thickness. For larger tadpoles, a spacer of 1–2 mm works best.

We have used several types of molds to shape the foods (Fig. 1). In most cases, we use the fiberglass window screen for a grid to measure the amount of food consumed during a trial. Without the screen, one can determine the amount of food consumed by weighing the food before and after the trial. It is our experience that the food will increase slightly in mass when placed in water, so control foods are necessary to factor out this effect. For small tadpoles, a very thin food coating is necessary for counting uncovered squares of screen. The thinnest and most even covering of the screening is obtained by placing the wax paper and screening directly between two plates of glass (Fig. 1A). The mixture of 4 g food to 0.75 g agar described above is enough to provide 400 cm^2 of food area using this technique. We have found that using a spacer for increasing the thickness of the food (such as in Fig. 1B) is only appropriate for larger tadpoles.

A similar method currently is being used by aquaculturists to raise commercial bullfrog larvae (D. Lester, pers. comm.). In this method, 4 g of kelgin, 2 g of sodium hexametaphosphate, and 168 g of commercial trout chow are combined and added to 1

liter of water. This solution is then spread onto a screen or put into a patty mold and allowed to solidify. Depending on the relative health of the metamorphosing froglets, differing amounts of soy protein, bone meal, and yeast are added to the trout chow. This method allows for the quantification of food consumption and prevents food from either fermenting in the tank or being filtered out as the water is cycled. Aquaculturists have used this method successfully in southwestern Louisiana for 15 years.

The advantages of this feeding technique for laboratory and mesocosm studies of tadpoles as well as for aquaculture include the ability to quantify the amount of food consumed by tadpoles, to localize the placement of foodstuffs, and to manipulate the chemical composition of the larval food. Another benefit that we have found is that food offered in this way is less likely to foul the water than an equivalent amount of flake food. Amounts of food consumed and the timing of food consumption are critical parameters in studies of the growth, development, and metamorphosis of anuran larvae. This technique can allow for more precise determination of food consumption at different stages of development. Alterations in the chemical composition of larval food, in particular the effects of potential plant defensive compounds on the growth of larval anurans, is an area that is largely unexplored. This technique may help facilitate more of these types of studies.

Acknowledgments.—We thank R. G. Jaeger for reviewing the manuscript. We are grateful to D. Lester for sharing his aquacultural experiences and his recipes for tadpole foods.

Special offer

Proceedings of the FitzSimons Commemorative Symposium
South African Lizards: 50 Years of Progress
and
Third H.A.A. Symposium on African Herpetology

The **Third H.A.A. Symposium on African Herpetology** was held at the Transvaal Museum in Pretoria from 11 to 15 October 1993. The proceedings have now been published in book form: ISBN 0-620-21569-0, 228 pages, A5 size, firm cover, glue & stitch bound. The first part of the book is dedicated to papers presented at the **FitzSimons Commemorative Symposium** held on the first day, celebrating 50 years since the publication of V.F.M. FitzSimons' 1943 monograph *The Lizards of South Africa*. In this section taxonomic changes which have occurred since 1943 in all southern African lizard families, as well as amphisbaenians, are reviewed by experts on the various taxa. Tables listing the taxa recognised by FitzSimons, together with currently recognised taxa, are presented for most families. Some accounts include summaries of all known life history and ecological data. A comprehensive listing of all papers published by FitzSimons is also included. The rest of the book comprises mainly extended abstracts of papers and posters presented during the remaining days of the symposium.

The book is now available from the Secretary/Treasurer (**P.O. Box 20142, Durban North 4016, South Africa**) at the special price of $20.00, postage and packaging included.

Non-lethal Technique for Obtaining Tissue for Molecular Studies of *Ambystoma* Salamanders

KIMBERLY D. CAMERON[1]
STEVEN B. BROYLES
and
PETER K. DUCEY[2]
Department of Biological Sciences, State University of New York at Cortland, Cortland, New York 13045, USA

[2] *Author for correspondence and reprints*

Electrophoretic analysis of allozymes has been used effectively in studies of the systematics, evolution, and ecology of salamanders (e.g., Bogart 1982; Bogart et al. 1987; Carter 1997; Shaffer 1984; Shaffer et al. 1991). In most studies, the tissues tested included combinations of heart, liver, and skeletal muscle, necessitating the sacrificing of individuals. Although such specimens may be useful as vouchers and additions to museum collections, many ecological or evolutionary studies could benefit from having a non-lethal technique for obtaining tissue samples for molecular analyses. We investigated whether the autotomized tail tips of salamanders could be used as tissue for allozyme electrophoresis.

Many salamander species autotomize parts of their tails in antipredator defense (Brodie 1977; Wake and Dresner 1966). When seized by a predator, the tail breaks intervertebrally with differing degrees of wound closure and little blood loss (Wake and Dresner 1966). Over time, salamanders regenerate nearly identical replicas of the original tail (Wake and Dresner 1966). Researchers should be able to simulate predator attack, inducing autotomy and obtaining tail tissue for analyses, in a manner that allows specimens to be returned to their natural populations. We examined whether tail tissue that has been sampled via autotomy is appropriate for electrophoretic identification of members of the *Ambystoma jeffersonianum* complex of mole salamanders.

The *Ambystoma jeffersonianum* complex consists of diploid (2n = 28) *A. laterale*, *A. jeffersonianum*, and polyploid female taxa of hybrid origin incorporating primarily *A. laterale* or *A. jeffersonianum* genomes, and in some cases genomes from *A. texanum* and *A. tigrinum* (Kraus et al. 1991; Lowcock et al. 1987; Uzzell 1964; Uzzell and Goldblatt 1967). *Ambystoma laterale*, *A. jeffersonianum*, and two triploid taxa (*A. (2)laterale-jeffersonianum*, *A. laterale-(2)jeffersonianum*) exist in New York State: *A. laterale* is found in the northern areas and on Long Island, whereas *A. jeffersonianum* is found in the southern parts of the state. A broad zone containing diploid species and unisexual taxa exists throughout central New York (Uzzell 1964; Uzzell and Goldblatt 1967). This complex of salamanders has been studied extensively since the early 1960's due to persistent questions regarding their evolutionary history, ecological roles, and reproductive biology.

Allozyme identification has been used to study polyploidy, gene flow, and hybridization in this complex of salamanders (Bogart 1982; Bogart et al. 1987; Kraus 1991; Uzzell and Goldblatt 1967). Morphological differences may suggest polyploidy, but cannot be reliably used to distinguish different ploidy levels (Lowcock and Bogart 1992; Lowcock and Murphy 1991). Flow cytometry of red blood cells can differentiate taxa based on ploidy, but cannot be used to determine evolutionary or phylogenetic history (Lowcock et al. 1991). Erythrocyte size measurements (Austin and Bogart 1982; Uzzell 1964), measurements of shed epidermal cells (Licht and Bogart 1987), and karyotype analyses (Sessions 1982) can indicate ploidy levels, but none of these techniques provides information on genome composition (Austin and Bogart 1982). Molecular techniques such as enzyme electrophoresis and mitochondrial DNA analysis are effective methods for determining ploidy levels, genome composition, and evolutionary relationships in *Ambystoma* salamanders (e.g., Bogart et al. 1987; Kraus and Miyamoto 1990). Currently, enzyme electrophoresis is preferred in some research projects because of its simplicity and cost effectiveness (e.g., Bogart et al. 1987; Kraus 1991; Kraus et al. 1991). We hypothesized that tissue from autotomized tail tips would be sufficient to allow us to correctly identify members of this complex via enzyme electrophoresis.

Material and Methods.—Nine salamanders of the *A. jeffersonianum* complex, collected as adults from Cortland County, New York (USA), were housed individually at 17–22°C. Each salamander was mildly agitated by prodding before a Boston clip (wire and folded metal clip for clamping stacks of paper) was placed on the distal 1/4 of the tail, causing almost immediate autotomy. Use of the clip allows salamanders to autotomize naturally along intervertebral planes which minimizes trauma and blood loss and maximizes speed of regeneration (Wake and Dresner 1966; PKD, unpubl. data). We froze each autotomized tail piece individually. Enzymes were extracted from small sections of tail tissue in 400µl of a 0.2 M Tris-Hcl (pH 7.5) extraction buffer. The enzyme extract was absorbed onto 4 mm x 8 mm wicks cut from Whatmann #MM chromatography paper. Samples were stored at -70°C until electrophoresis could be performed.

Wicks were loaded into 10% starch gels. A Clayton-Tretiak buffer system (pH 6.1; Clayton and Tretiak 1972) was used to resolve aspartate aminotransferase (AAT), malate dehydrogenase (MDH-1,2), and superoxide dismutase (SOD). All three enzyme stains have been used in previous electrophoretic studies of *Ambystoma* salamanders and were useful in diagnosing species within the *A. jeffersonianum* group (Bogart et al. 1987; Elinson et al. 1992; Taylor 1992). Staining protocols were identical to those described by Wendel and Weeden (1989). Allozymes were scored in a manner consistent with Taylor (1992).

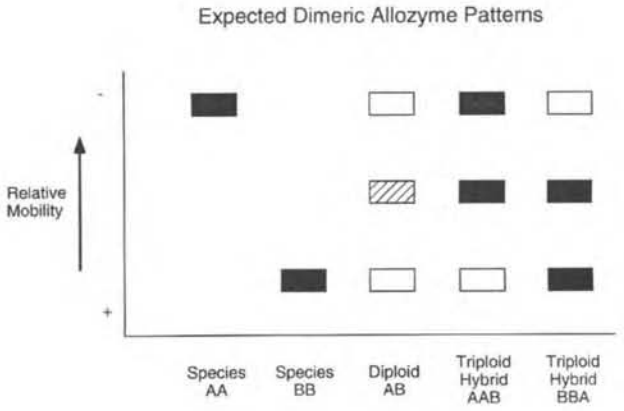

FIG. 1. Expected dimeric allozyme patterns for parental homozygotes (AA and BB), heterozygotes or diploid hybrids (AB), and triploid hybrids (AAB and ABB). The box fill patterns represent the relative staining intensities within individual genotypes. Open boxes have a stain intensity of 1, cross-hatched boxes a stain intensity of 2, and filled boxes a stain intensity of 4.

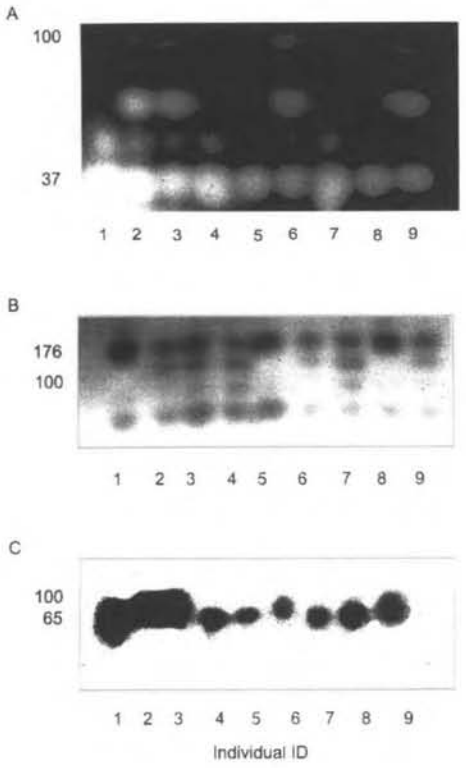

FIG. 2. Electrophoresis gels for three enzymes from nine individuals of the *Ambystoma jeffersonianum* complex: (A) superoxide dismutase (SOD-1); (B) malate dehydrogenase (MDH-1 and MDH-2); aspartate aminotransferase (AAT). rf values are shown to the left of each gel.

We used unbalanced stain intensities of allozymes to predict the genomic composition and ploidy level of each salamander (Danzmann and Bogart 1982). For example, a diploid salamander that is heterozygous for a dimeric isozyme will appear 3-banded with a relative stain intensity of 1:2:1 (Fig. 1). A triploid hybrid salamander with two homozygous genomes from parental species 1 and one genome from species 2 will also appear 3-banded, but with a relative stain intensity of 4:4:1 (Fig. 1). This result is due to the unequal genomic contribution of both parental species and random combination of protein subunits in constructing active dimeric enzymes. Tetraploid individuals are known to occur at low frequencies in some populations (Bogart et al. 1989; Lowcock et al. 1991). Their allozyme patterns should be readily distinguishable from those of the triploids (Danzmann and Bogart 1982). For example, a tetraploid with three genomes from one parental species should express a 9:6:1 stain intensity ratio for dimeric isozymes such as MDH-1 and SOD-1. A balanced tetraploid will express a stain intensity ratio of 2:4:2 for these isozymes, which is, however, indistinguishable from a diploid heterozygote (1:2:1).

We attempted to corroborate our electrophoretic determination of polyploid hybrids through a double-blind examination of erythrocyte size. Erythrocytes of diploid *Ambystoma* salamanders range in area from 500–900μm^2 while erythrocytes of polyploid salamanders range from 700 to 1500μm^2 (Austin and Bogart 1982; Uzzell 1964). However, most individual studies have shown little or no overlap in diploid and polyploid cell areas suggesting some variability is due to differences in laboratory techniques (Austin and Bogart 1982; Bogart et al. 1987). In our study, one researcher collected approximately 100µl of blood from each salamander by clipping a single toe and placed it in 0.7% saline solution. Another researcher measured the diameter of 10–15 erythrocytes from each sample using a light microscope with an ocular micrometer. Areas were determined by assuming the shape of an erythrocyte to be elliptical.

Results and Discussion.—Electrophoretic analysis of tail tissue resulted in clearly recognizable banding for all individuals and yielded evidence of polyploidy in four of the nine salamanders. Five salamanders (ID #1, 4, 5, 7, and 8) were homozygous for a slow-moving SOD-1 allozyme (r_f = 37), indicating diploid *A. jeffersonianum* (Figs. 2A, 3A). Four individuals (ID #2, 3, 6 and 9) exhibited both slow and fast (r_f= 100) allozymes with staining intensity ratios of 1:4:4 (Figs. 2A, 3A). Numerous studies have documented that *A. laterale* possess the fast SOD-1 allozyme (rf = 100), that *A. jeffersonianum* possess the slower allozyme (rf = 37), and that the staining intensity patterns of 1:4:4 which we found represent triploids with two *A. jeffersonianum* genomes and one *A. laterale* genome (LJJ) (Bogart et al. 1987; Elinson et al. 1992; Kraus and Miyamoto 1990). Our results for the MDH and AAT loci supported the results for the SOD-1 locus (Figs. 2B and C; 3B and C). MDH-2 appeared monomorphic among the nine

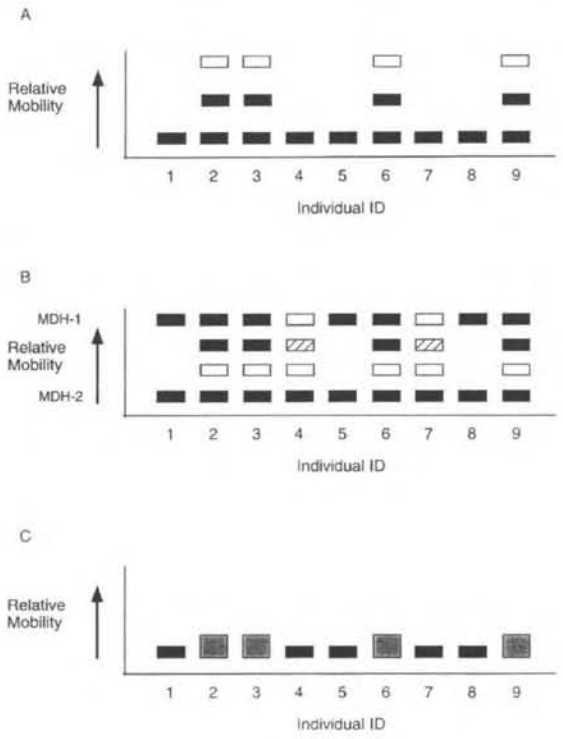

FIG. 3. Interpretation of gels in Fig. 2. (A) Allozyme patterns for superoxide dismutase (SOD-1). Individuals 1, 4, 5, 7, and 8 appear to represent diploid individuals of *Ambystoma jeffersonianum*. Individuals 2, 3, 6, and 9 appear to represent triploid hybrids with two *A. jeffersonianum* genomes. (B) Allozyme patterns of malate dehydrogenase (MDH-1 and MDH-2). No variability was exhibited for MDH-2. Individuals 1, 5, and 8 appear to represent diploid individuals of *A. jeffersonianum* that are homozygous for MDH-1. Individuals 4 and 7 are heterozygous at MDH-1. Individuals 2, 3, 6, and 9 appear to represent triploid hybrids with two *A. jeffersonianum*. (C) Allozyme patterns of aspartate aminotransferase (AAT). A wide, indistinct band (represented by a lighter filled box) was observed for individuals 2, 3, 6, and 9. Box fill patterns are the same as in Fig. 1.

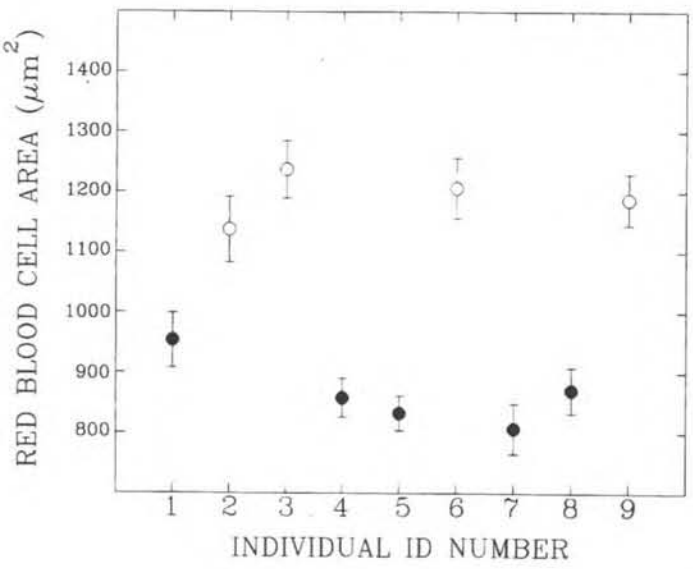

FIG. 4. Means (standard error) for erythrocyte area from nine individuals of the *Ambystoma jeffersonianum* complex. Individual ID numbers correspond to the same numbers represented in the allozyme profiles of Figs. 2 and 3. Putative diploids are represented by hollow circles and putative triploids are represented by filled circles.

specimens examined. MDH-1 was polymorphic: three individuals (ID #1, 5, and 8) were homozygous for the fast moving allozyme (rf = 176) (suggesting diploid *A. jeffersonianum*; Bogart et al. 1987), four individuals (ID #2, 3, 6, and 9) additionally had a slower allozyme (rf = 100) and 4:4:1 staining intensity patterns (suggesting polyploidy LJJ; Bogart et al. 1989), and two individuals (ID #4 and 7) were heterozygous with 1:2:1 staining intensity patterns. MDH-1 variation for individuals 4 and 7 is probably representative of diploid *A. jeffersonianum* rather than diploid hybrids as diagnostic *A. laterale* allozymes were absent at SOD-1 and AAT loci. Previously studied populations of *A. jeffersonianum* were homozygous for the faster MDH-1 allozyme (Bogart et al. 1987; Shaffer et al. 1991; Taylor 1992), hence our results may indicate some level of meiotic recombination within the unisexual taxa as has been suggested by others (Kraus and Miyamoto 1990; Sessions 1982). For AAT, our results were inconclusive (Figs. 2C, 3C), but only individuals 2, 3, 6, and 9 showed wide indistinct bands. Taken together, our results for these three enzymes were sufficient to hypothesize that four individuals (ID #2, 3, 6, and 9) were polyploid, possessing a single *A. laterale* and two *A. jeffersonianum* genomes.

To test these ploidy designations, we compared the allozyme results with measures of erythrocyte area. Erythrocyte areas for the four proposed polyploids (range of individual mean areas 1138–1238 μm^2) were considerably larger than for the proposed diploids (range 807–954 μm^2; Fig. 3). These results are consistent with previous studies that demonstrated significantly larger erythrocytes in polyploid members of the *A. jeffersonianum* complex (Austin and Bogart 1982; Uzzell 1964) and support the validity of our electrophoretic results.

Allozyme electrophoresis has proved an effective method for identifying ploidy and genomic composition in *Ambystoma* salamanders (e.g., Bogart, et al. 1987; Kraus and Miyamoto 1990; Lowcock and Bogart 1992). The present study demonstrates that diagnostic allozyme analysis in the *A. jeffersonianum* complex can be accomplished without lethal sampling to obtain heart, spleen, and liver tissue. By utilizing autotomized pieces of salamander tails, researchers can obtain sufficient enzyme activity, test representative sample sizes, and still cause only limited disturbance of natural populations. Because many herpetofaunal populations are already under severe pressure, non-destructive techniques, like those presented here and elsewhere (e.g., Gonser and Collura 1996; Licht and Bogart 1987; Lowcock et al. 1987), should become standard tools for genetic studies of amphibian populations.

Acknowledgments.—We thank B. Shaffer and F. Kraus for their useful criticisms of the manuscript and David Munson for help in the collection of animals.

Studies on breeding success using multilocus DNA fingerprinting in lizards are rare and DNA ordinarily is obtained from blood samples (Olsson et al. 1994, 1996). However, blood sampling in lizards can be difficult, especially in small individuals, and may not provide sufficient high molecular weight DNA for fingerprinting. Blood has been obtained from the orbital sinus (Moore 1986), tail cuts (Tokarz 1987), a minute cut in the corner of the mouth (Olsson et al. 1994), or the caudal vein (Wilson and Wingfield 1994), but this manipulation could cause injury or haematoma and the amount of blood taken might affect some traits in study animals.

In our studies with *Psammodromus algirus*, we tried the above methods and found that the most efficient blood sampling was from the caudal vein. However, in subadult and juvenile individuals the amount of blood obtained is insufficient for some procedures. Here, we present an alternative method of DNA extraction from tail fragments, as autotomy (tail separation) may occur in nature and might not represent a significant handicap to the individual animals manipulated.

Five adult individuals of *P. algirus* were captured near Navacerrada (Madrid province, Spain). Tails from these individuals were removed and stored in absolute ethanol at 4°C until pro-

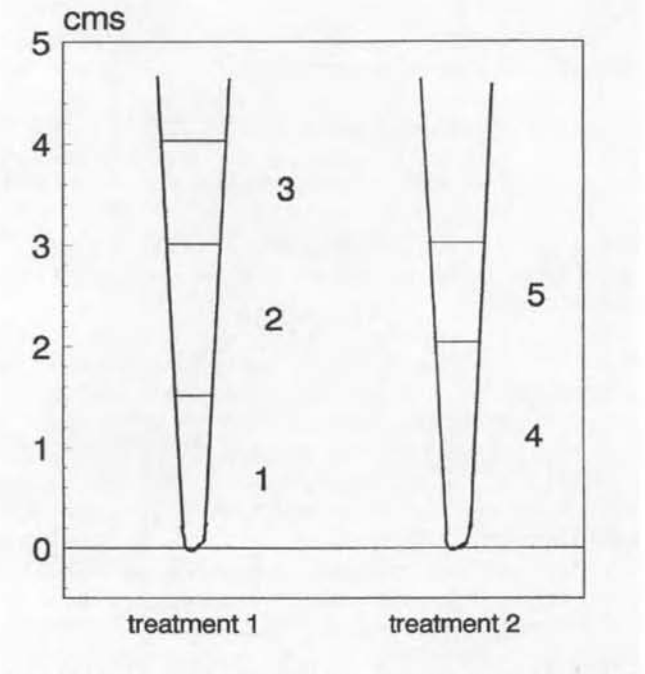

FIG. 1. Tail fragments analyzed. Treatment 1. Each individual tail was cut in three fragments: Fragment 1, from tip up to 1.5 cm; fragment 2, between 1.5 and 3 cm; fragment 3, between 3 and 4 cm. Treatment 2. Each individual tail was cut in two fragments: Fragment 4, from tip up to 2 cm; fragment 5, between 2 and 3 cm.

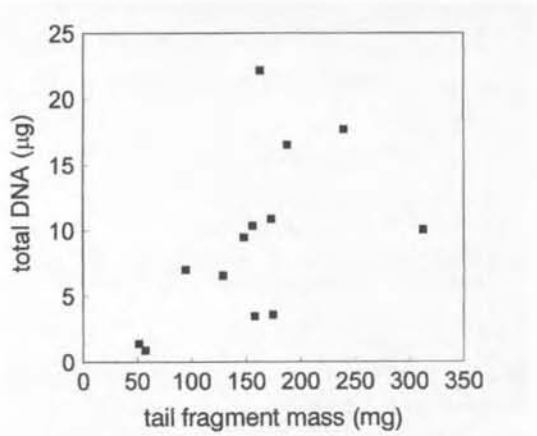

FIG. 2. Relationship between DNA content and tail fragment mass.

cessed. To assess the minimum size of tail fragment necessary to isolate adequate amounts of DNA for fingerprinting, tails were cut in two different ways. In treatment 1, we made cuts in three individuals (A–C) at 1.5, 3, and 4 cm from the tip of the tail. In treatment 2, we cut tails of two individuals (D, E) at 2 and 3 cm from tip of the tail (Fig. 1). A sample of 30 µl of blood, stored in absolute ethanol, was used as a standard for comparison. Tail fragments were dried on Whatman paper to remove the ethanol, weighed, and digested separately in 650 ml SET buffer (150 mM NaCl, 50mM Tris/HCl pH 8.0, 1mM EDTA Na_2 pH 8.0), 15 µl proteinase K (20 mg ml^{-1}) and 7.5 µl of 250 g l^{-1} SDS and incubated overnight at 55°C. DNA was purified by one extraction with phenol, followed by one with phenol/chloroform and one with chloroform iso-amyl alcohol (24:1). It was then precipitated with 0.1 volumes 3M sodium acetate and 2 volumes of cold (-20°C) absolute ethanol and pelleted at approximately 11,000 rpm for 5 min. The DNA was washed with 75% ethanol, dried at 37°C for 30 min and resuspended by overnight incubation in TE (1mM EDTA Na_2, 10mM Tris/HCl, pH 8.0). The amount of buffer added for resuspension ranged from 20–70 µl, depending on the size of the DNA pellet. 15 µl of the redissolved DNA was digested with 10U of Hae III in the presence of 4 mM spermidine, according to manufacturer instructions. The concentration and size of cut DNA was assessed by fluorometer and mini-gel. The mini-gel was prepared in 1x TAE (40mM Tris, 40 mM acetic acid, 1 mM EDTA Na_2) with .8% LE agarose, stained with 0.5µg.ml^{-1} Ethidium Bromide and electrophoresed for 30 min at 100V. Uncut and cut DNA from tail fragments together with Lambda DNA - Hind III markers were revealed by UV light.

High molecular weight DNA (>23 Kb.) was obtained from all samples analyzed. Distal tail fragments of 1.5 cm weighing 52–95 mg produced 0.89–7.03 µg DNA, whereas distal tail fragments of 2 cm and 129–156 mg yielded 6.58–10.37 µg (Table 1). Although 1.5 µg of DNA may be enough to obtain a minisatellite DNA (May et al. 1993), we considered 5.0 µg as the minimal amount of total DNA per sample necessary to obtain predictable results. Therefore, the shortest distal fragments (1.5 cm) did not yield sufficient DNA for minisatellite analysis. Longer distal fragments (2 cm) were more than enough to run one or two gels, 3 cm of tail (fragments 1+2 or 4+5) produced sufficient DNA for several assays, a necessity when the same individual must be scored in different family assemblages.

We plotted the amount of DNA produced versus fragment mass (r_s= 0.65, N = 13, p = 0.017) to obtain predictable estimates of fragment size required for adequate DNA collection. The lower limit mass to yield 5 µg of DNA corresponded about to 80 mg of tail fragment (Fig. 2). In our experiment, 2 cm of tail fragment produced more DNA than 30 µl of blood (Table 1), a volume which is available only from large individuals (unpubl. data).

Different genetic assays require different amounts of DNA. For example, PCR amplification for microsatellites or sequencing requires small quantities of template DNA, in the order of nanograms. As shown in Table 1, any of the fragments in our analysis produced more than enough genomic DNA for these amplifications.

TABLE 1. DNA yield obtained from tail fragments of five individuals (A–E) of *Psammodromus algirus* according to segment position (1 to 5, Fig. 1) and mass.

Individual	Tail fragment	Mass (mg)	Total DNA (µg)
A	1	58	0.89
A	2	158	3.50
A	3	175	3.60
B	1	52	1.40
B	2	148	9.50
B	3	173	10.90
C	1	95	7.03
C	2	240	17.70
C	3	313	10.06
D	4	129	6.58
D	5	163	22.17
E	4	156	10.37
E	5	188	16.53
BLOOD	—	30µl	7.28

Our sampling method can be used for species with autotomy in which bleeding may be difficult or traumatic. Although tail loss may reduce home range size and movement rates in *P. algirus* (Salvador et al. 1995), this effect was recorded only in males with a regenerated tail shorter than 150 mm (Salvador et al. 1996). As the length of intact tail in this species may reach 200 mm in adults, the consequences of removing fragments of 2–3 cm for DNA sampling may be negligible. The use of this sampling method in other species of lizards with caudal autotomy is recommended if the fragment of tail removed produces enough DNA and does not modify the behavior or any component of fitness of the species under study.

Use of a Fluorescent Marking Technique on Small Terrestrial Anurans

MARTIN A. SCHLAEPFER
Department of Natural Resources, Fernow Hall, Cornell University
Ithaca, New York 14853-3001, USA

The choice of a marking technique for research should be based on the objective of the study, effectiveness of the technique, ease of application, and the potential risk to the organism. While toe-clipping is convenient and inexpensive, and thus remains a common technique for marking adult anurans (Donnelly et al. 1994), there is some evidence that it may affect behavior or survivorship (Clark 1972; Golay and Durrer 1994; but see Lemckert 1996). The use of a marking technique that potentially affects the organism's behavior or survival is usually unacceptable; thus, alternatives to toe-clipping should be considered. Marking amphibians with fluorescent pigments appears to be a promising alternative (Donnelly et al. 1994; Windmiller 1996). A pressurized application of fluorescent powder was applied successfully to aquatic and terrestrial salamanders (Ireland 1973, 1991; Nishikawa and Service 1988; Taylor and Deegan 1982). However, the effectiveness, details of application, and risks of this technique have not been quantified for other amphibians.

I recently used a pressurized fluorescent marking technique on small terrestrial leaf-litter frogs (*Eleutherodactylus podiciferus*; Leptodactylidae) in Costa Rica to evaluate its applicability. Inert fluorescent powder was applied to a hind leg of frogs using a pressurized source of air similar to that described in Nishikawa and Service (1988). However, Nishikawa and Service (1988) used a small 2-liter source of pressurized N_2, whereas I used a source of pressurized air delivered by a SCUBA tank. The nozzle of the spray gun was modified to accommodate a variety of interchangeable nozzle openings. The 7/64 inch (2.8 mm) opening was optimal, as it did not clog the nozzle yet produced a concentrated point. The yellow, fluorescent, granular powder (50–350 mm) produced a mark 3–4 mm in diameter on the hind leg of the frog when delivered at a pressure of 100 psi, approximately 0.5 cm from the skin.

I compared the use of fluorescent pigments in the field to toe-clipping with respect to i) ease of application and disturbance to frogs, ii) risk to frogs (i.e., survival), iii) longevity of the mark, and iv) logistics and cost. I caught and marked 68 adult *E. podiciferus* (10–24 mm SVL) in 1996, alternating between the fluorescent powder technique, and toe-clipping a single foot digit (digit IV). Clipped toes were disinfected with a dab of Bactine® to reduce the likelihood of infections (Martin and Hong 1991). Juveniles (< 10 mm SVL) were judged to be too fragile to mark with either method. Frogs were marked during two Periods: Period I, 2–8 July: 22 yellow-marked and 23 toe-clipped frogs were released; Period II, 20–23 July: 11 yellow-marked and 12 toe-clipped frogs were released. To determine whether marks were disappearing, a description of each individual's natural markings (modified from Savage and Emerson 1970) were noted, as well as SVL. Frogs were recaptured during Period II and Period III (13 August).

The pressurized powder technique was more difficult to apply, and seemingly more harmful to the frogs than toe-clipping. Applying the pigment required holding the frog tightly on a flat surface and then releasing a blast of air. If the frog was not properly immobilized, legs were occasionally dislocated by the blast (N = 5; 15%). Also, frogs were occasionally blown away, literally. One frog died due to the fluorescent powder procedure, and 30–50% of the frogs appeared to be stunned to various degrees by the blast of air. Recovery from the blast, measured by a return to a righting position and the ability to jump when touched, was often incomplete several minutes later. *Eleutherodactylus podiciferus* may have been particularly susceptible to the blast of air due to its small size. Toe-clipping was easier and quicker to apply than the pressurized powder, although it would not have been possible to clip the smaller, inner toes (I–III) on the younger individuals (<18 mm SVL) due to their small size. Fingers are also very small and would be difficult to clip for the same reason (pers. obs.). None of the toe-clipped frogs suffered visibly from the clipping procedure.

Eleven of the 68 marked frogs were recaptured. Six were toe-clipped and 5 bore yellow fluorescent spots (Period II: 2 toe-clipped and 3 yellow from Period I; Period III: 2 toe-clipped from Period I, 2 toe-clipped from Period II, and 2 yellow from Period II). No toe-infections or other effects of either technique were observed on recaptured individuals. I was unable to detect any significant difference in survivorship between the two marking methods, because of low recapture rates.

Yellow spots were still clearly visible on 3 of 5 recaptured frogs with these marks. The other two had faded to a light gray spot during the three weeks since the application, but were still visible, particularly under UV light. Nishikawa and Service (1988) found that fluorescent marks on salamanders would last 1–2 years in the laboratory. Toe-clips were still clearly visible on the two individuals marked in Period I and caught in Period III, suggesting that they do not regenerate within a 5–6 week period. No unmarked individuals fit the profile of a previously marked individual (using natural variation and SVL); thus, no lost yellow marks or regenerated toe-clips could be confirmed among the recaptured individuals.

I agree with Ireland (1991) that the equipment was rather cumbersome to transport into the field, weighing 3.2 kg excluding the source of air (a SCUBA tank and the regulator). It was also expensive, costing US$ 340 in 1996 (including UV lamp, but excluding the price of the SCUBA tank and the regulator). Toe-clipping required a pair of surgical scissors and a bottle of Bactine® (weight: 120 g; cost: $12).

It appears that toe-clipping is easier, less harmful, more convenient, and less expensive to apply to *E. podiciferus* than pressurized fluorescent powder. Fluorescent marking has the advantage that marked organisms may be identified by day, or by night using a UV lamp, without further handling. Nishikawa and Service (1988) also found higher rates of recapture per unit effort of salamanders that had been marked with fluorescent powder relative to other studies that used toe-clipping. Fluorescent powder may

therefore still present an interesting alternative technique for marking larger frogs, which can be properly immobilized and which are less likely to suffer from the blast of air during the application of the powder. I concur with Donnelly et al. (1994) who recommended that researchers test a variety of techniques on their organism prior to adoption for field or laboratory studies, because effectiveness and application will vary with body size and life history.

Acknowledgments.—Financial support was generously provided by the Guani Family Fellowship in Conservation Biology, a pre-doctoral NSF fellowship, and OTS-Las Cruces. Special thanks to the Guani family and R. Carnahan for their logistical support; to the Gamboa family for the permission to work on their land; to T. Gavin, K. Adler, and M. Donnelly for helpful comments on earlier drafts of this manuscript; to the Costa Rican government for permission to study; and to the staff at Cornell's Metal Shop for the modifications made to the spray gun.

Abstract.—How a radio, sonic, or satellite transmitter is attached to a turtle or tortoise may affect the transmitter's transmission range and the animal's behavior, survival, and reproductive success. We reviewed 113 scientific papers, reports, and semi-technical articles reporting on radio-tracking projects with turtles and conclude that little information is available in the literature to evaluate the effects of transmitters on the study animals. We also provide step-by-step directions on a successful method we used to attach transmitters to desert tortoises (*Gopherus agassizii*) that minimizes potential of affecting the animal's behavior, physiology, reproduction, or survival while maximizing distance of transmission. We believe this method can be used on many other species of turtles and tortoises.

Biotelemetry has become indispensable for studying turtle migration, dispersal, home range, habitat use, physiology, and the effectiveness of relocation efforts. The most common types of telemeters used on turtles are radio, sonic, and satellite transmitters, which each have advantages depending on the specific applications. An important consideration for using radio transmitters and all marking techniques is assuring they do not affect significantly the behavior, physiology, reproductive success, and survival of the animals (Anonymous 1987; Brander and Cochran 1969; Ireland and Kanwisher 1978; Kaufmann 1992a; Renaud et al. 1993b; Schubauer 1981; Schwartzman and Ohmart 1977). Therefore, non-invasive methods of transmitter attachment must be developed and tested (Anonymous 1987). Furthermore, as there are tradeoffs between transmitter weight, transmitter longevity, and transmission range (Brander and Cochran 1969; MacDonald and Amlaner 1980), transmitter attachment methods should be developed to optimize performance to meet study objectives.

We reviewed 113 published and unpublished accounts of the use of radio, sonic, and satellite tracking of turtles to determine the attachment methods used and to identify problems for the study animals caused by the transmitters. We also outline the method we have used for five years to attach transmitters to desert tortoises (*Gopherus agassizii*) without causing physical harm to the study animals, while maximizing transmitter longevity and range. This method can be used for multi-year applications with other species of turtles.

Review of Transmitter Attachment Methods and Their Problems.—In the 113 publications, articles, and reports we reviewed, radio transmitters, which consist of three major components (body

of transmitter, battery, and antenna), were attached externally to the carapace of turtles by several means: cemented on with epoxy, silicone sealant, dental acrylic, or some other adhesive; strapped on with harnesses; or attached via bolts, wire, cable or nylon ties, or monofilament line passed through holes drilled in the carapace, usually through the posterior carapace or marginal scutes (Table 1). These methods were used to attach either the transmitter and battery directly to the carapace or to allow the transmitter to trail loosely behind the animal.

Some less conventional modes of attachment were used. In one instance, transmitters were sewn onto the carapace of soft-shelled turtles (Plummer and Shirer 1975). Transmitters also were attached with some success using black plastic electrical tape (Eckler et al. 1990; Moll and Legler 1971). Whereas implantation is the norm in snakes (Fitch and Shirer 1971; but see Ikeda et al. 1979), it has been rarely employed in turtles (Table 1). Many authors (23%) did not mention how or where transmitters were attached, making it difficult to evaluate the potential effect of the transmitter on the animals, and hence the possible limitations on interpreting study results.

Problems caused by transmitters are well documented for birds and mammals (Kenward 1987; White and Garrott 1990), but are poorly known for turtles. We know of only three limited studies designed in part to test the effects of different transmitters or attachment methods on turtles. Timko and Kolz (1982) estimated that a satellite transmitter caused a captive loggerhead turtle to spend twice as much time on the water surface, but concluded the transmitter caused no "radical" change in behavior. However, their sample size was one, and no control was reported. Kemmerer et al. (1983) found that after equipping 20 loggerhead turtles with transmitters, the turtles spent more time on the surface during the first 3 days than the following 17 days of study. Beavers et al. (1992) found three different adhesive attachment methods had no effect on loggerhead turtle behavior, but their sample size was one per method and they made no mention of methods or criteria.

We located six papers reporting problems observed during the course of field studies with turtles. Keinath and Musick (1993) reported the transmitter and harness cemented to a leatherback turtle (*Dermochelys coriacea*) were bitten by a tiger shark (*Galeocerdo cuvieri*), the resultant damage causing the harness to chafe the turtle's skin. Equipment poorly attached to harnesses slapped against and severely damaged the carapaces of leatherback turtles (Eckert and Eckert 1986). Implanting transmitters into the oviducts of northern long-necked turtles (*Chelodina rugosa*) caused oviducal adhesion in at least two turtles, reducing reproductive output in the year studied, and the surgical procedure resulted in the death of one turtle (Kennett et al. 1993). The act of attaching transmitters may have caused up to 55% of female yellow mud turtles (*Kinosternon flavescens*) to move to new nesting locations (Iverson 1990); the transmitter attachment method was not noted, however. Brill et al. (1995) found submergence behavior of green turtles (*Chelonia mydas*) was affected for up to three hours after they attached transmitters to the rear marginals of the carapace by inserting nylon straps (tie-wraps) through drilled holes. Some shell deformation occurred in hatchling gopher tortoises (*Gopherus polyphemus*) because epoxy holding on the transmitters encroached growth areas between scutes (Butler et al. 1995). On the other hand, Hopkins and Murphy (1981) reported no damage to carapace or flippers from transmitters on 37 loggerhead turtles.

Although not published, other problems have occurred. For instance, J. Congdon (pers. comm.) found transmitters placed on the carapaces of painted turtles (*Chrysemys picta*) became entangled in filamentous algae preventing the turtles from diving. C. K. Dodd, Jr. (pers. comm.), has made similar observations on common mud turtles (*Kinosternon subrubrum*). H. Avery (pers. comm.) observed female desert tortoises impeded by transmitters, which were mounted on the anterior carapace, that got hooked by stems of desert shrubs. We found one desert tortoise shell that became deformed because normal shell growth was inhibited by a transmitter antenna that was attached improperly for one year. Similar results from desert tortoises were reported by K. Berry (pers. comm.) and A. Karl (pers. comm.). Such deformation is most likely to occur in animals that experience relatively rapid growth during the course of study (e.g., juveniles or animals equipped for several years). Although unreported, drilling holes into the shell and underlying bone may lead to potentially harmful infection, and this effect may not be observable until sometime after the transmitters have been removed (B. Homer, pers. comm.). Bertram (1979) did comment on the absence of any wounds after removing a transmitter that had been bolted onto the carapace of a hingeback tortoise (*Kinixys belliana*) two years earlier.

Transmitters may attract the attention of predators (Keinath and Musick 1993; cf. Renaud et al. 1993b) or people (Stoneburner 1982). To reduce the potential for such effects, transmitters should be camouflaged in some way. For instance, Dizon and Balazs (1982) covered their transmitters with roofing tar and sand before attaching to Hawaiian green turtles (*Chelonia mydas*). Schwartzman and Ohmart (1977) mixed neutral color compounds to the epoxy or painted the dried epoxy after attachment to desert tortoises. Satellite transmitters placed on sea turtles are routinely painted black (C. K. Dodd, Jr., pers. comm.).

Authors occasionally mention transmitter failures, problems, or malfunctions (Table 1), but rarely are the causes known, mentioned, or hypothesized. We found several accounts in the literature of the loss of transmitters. Stoneburner (1982) laments the theft of seven out of eight buoy transmitters attached to loggerhead turtles (*Caretta caretta*). Timko and DeBlanc (1981) lost 4 of 22 transmitters and Timko and Kolz (1982) lost their only transmitter when the linen lanyard used to attach floating transmitters to Kemp's ridley turtles and a loggerhead turtle became abraded and parted (see also Renaud et al. 1992; Renaud et al. 1993b; Renaud and Carpenter 1994; Schubauer 1981). After being in place for five months, the vertically-protruding antenna broke off a transmitter attached to a hingeback tortoise (*Kinixys belliana*, Bertram 1979). In one study of the desert tortoise, 9% of transmitters (10 of 111) fell off the animals over four years (EG&G 1993).

Attaching Transmitters to Desert Tortoises.—For nearly two decades, researchers have been attaching transmitters to the carapaces of desert and gopher tortoises with epoxy cement (for example, see Schwartzman and Ohmart 1977). We modified the methods used by Schwartzman and Ohmart (1977), Mike Cornish (pers. comm.), Charles Peterson (pers. comm.), and others to attach radio transmitters securely to desert tortoises apparently without causing shell deformation, predator attraction, mating disruption, or transmitter loss, while also yielding greater transmitter range. We present the following step-by-step description of the protocol we used so that the method can be adapted to other species of turtles and tortoises.

We used three different types of transmitters depending on the size of the tortoise. Two-stage battery-powered transmitters (AVM Instruments SB-2*), weighing 35 g, were attached 108 times to 43 tortoises (171–296 mm midline carapace length [MCL], 1075–5200 g). One-stage battery-powered transmitters (AVM Instruments SM-1H), which are smaller (26 g) and weaker, were at-

tached 24 times to 14 tortoises between 146 and 239 mm MCL (800–3150 g). One-stage solar-assisted transmitters (AVM Instruments SM-1H-solar), weighing 4.2 g, were attached 41 times to 21 immature and subadult tortoises between 97 and 207 mm MCL (220–1800 g). Whip antennas on the larger two transmitters ranged from 280 to 320 mm in length and were made of 20 gauge, insulated, stranded wire. The whip antennas for the solar transmitters were 150 mm long and made of single 24 gauge, insulated, stranded wire.

We used the following step-wise procedure to attach the non-solar assisted transmitters to 57 desert tortoises (Fig. 1a):

1. We tested the transmitter to confirm that it worked.
2. All dirt was brushed off of the carapace.
3. We pre-positioned the transmitters to the first left or first right costal scute of the tortoise's carapace, as flush to the carapace as possible.
4. To position the antenna, we cut short sections of flexible 3 mm plastic tubing, and epoxied each section to the first four vertebral scutes (see also Butler et al. 1995). Each section was cut slightly shorter than its associated scute. Super glue was used to hold each section of tubing in place while we applied a quick drying, pliable putty epoxy (Power Poxy Adhesives, Inc., Power Poxy® #40001*) over each section of tubing in a continuous layer from the scute surface on one side of the tube to the scute surface on the opposite side of the tube. We were cautious not to get any epoxy on the scute sutures or on neighboring scutes.
5. We ran the antenna through the tube sections leaving approximately 50–120 mm of antenna hanging loose beyond the posterior of the animal.
6. The transmitter was then attached with putty epoxy, using care not to bridge the scute margins. Spaces between the transmitter and carapace were filled in with epoxy to prevent the transmitter from getting caught in vegetation.
7. Both the transmitter and the putty epoxy were painted with a flat colored, lead-free paint to reduce reflectivity and contrast.
8. Finally, the transmitter was checked again for proper operation and the tortoise was released immediately.

The entire procedure takes approximately 15 min. The transmitters were removed about every two years for battery replacement by cutting through the epoxy with a pocket knife, a simple process that took less than 10 min.

Using similar procedures, solar-assisted transmitters were attached to the fifth vertebral scutes of 21 tortoises using putty epoxy, but the antenna was left loose. We did not use any tubing to attach the antenna to the tortoise. Some transmitters were attached with the antenna oriented vertically and others horizontally.

To simplify and expedite transmitter removal during future scheduled battery replacement, we initially attached a brass base plate with Devcon® Five-Minute Epoxy®* to the carapace, then attached the transmitter to a metal post on the plate. Transmitters attached in this manner became detached 22 times between day 1 and 26 months later. No additional losses were experienced after eliminating use of the brass plate (i.e., using the methods described above).

For the first two years, we attached the antenna to the marginals, partially encircling the animal. Later, we began attaching the transmitter to the first right or left costal, as described above, which facilitated placement of the antenna over the vertebral scutes and letting the distal 50–120 mm of antenna trail behind the tortoise. This improvement increased transmission range by approximately 20% (pers. obs.). Diverting the antenna down to the last one or two costal scutes on females would keep it from possibly interfering with copulation, although we have observed unimpeded copulations with the antenna attached to all vertebral scutes. Leaving antennas loose on solar-assisted transmitters caused antennas to break 19 times, but was necessary to maximize the range of these weaker transmitters. Vertical orientation of antennas also resulted in greater range compared to horizontal orientation, but made the antenna more vulnerable to breakage. To reduce the breakage problem, a smaller, more resilient gauge antenna was used and the base of each antenna was enclosed in a small spring.

Placed on the vertebrals, the tubing allowed the antenna to be pulled through the tubes as the tortoise grew, thus preventing shell deformation. We have attached antennas in this manner to 57 tor-

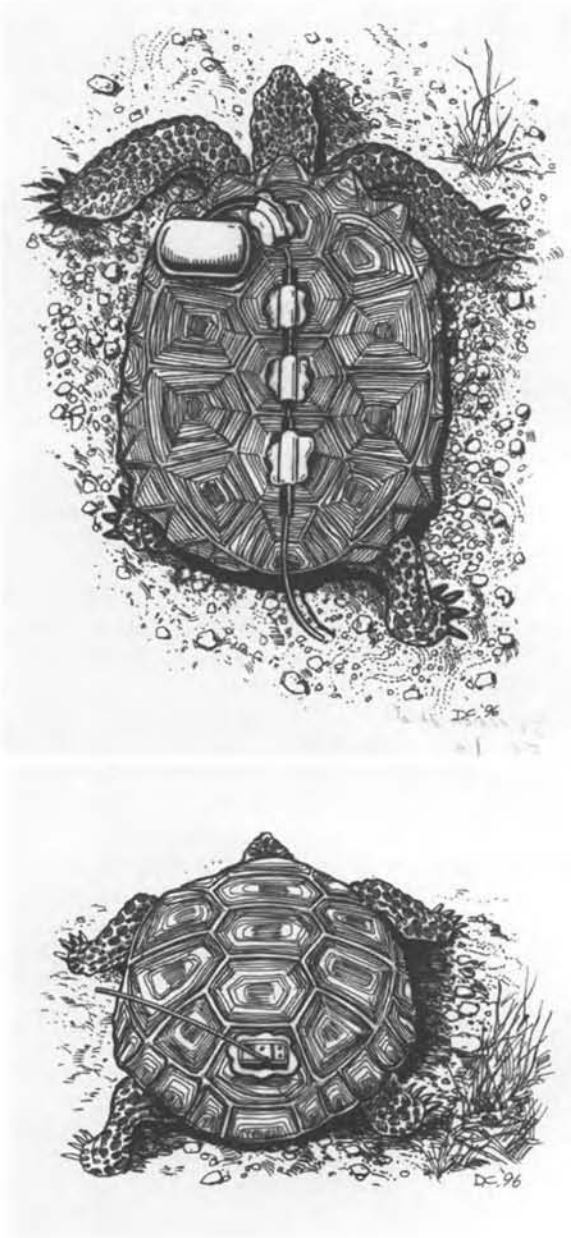

FIG. 1. Drawing showing how we attached radio transmitters to the carapaces of desert tortoises: (a) larger battery-powered transmitters were attached to tortoises larger than 146 mm (midline carapace length; 800 g) and (b) smaller solar-assisted transmitters were attached to immature and subadult tortoises between 97 and 207 mm (220–1800 g).

TABLE 1. Methods of transmitter attachments in chelonians. Methods are categorized as one of the following classifications: "adhesive" (transmitter was attached to the shell of the turtle with glue, epoxy, dental acrylic, or fiberglass), "harness" (transmitter was strapped around the shell without otherwise disturbing the shell), "hole in shell" (holes were drilled, screwed, or punched through the shell, and bolts, string, wire or other filament was strung through the hole[s] to attach the transmitter), "implantation" (transmitters were surgically implanted within the body), "tape" (transmitter was attached with electrical tape), "sewn" (the transmitter was sewn into the shell of a soft shell turtle), or "not mentioned" (method was not evident). Papers that reported on problems are indicated by superscripts. An "*" notes data on effect of the transmitter on the health, development, behavior, or ecology of the turtle. A "+" denotes problems with transmitters falling off or otherwise being lost from the turtle. A "†" notes a non-specified problem with transmitter use on a turtle.

toises for up to five years, and have observed only one shell that became slightly deformed when the widened distal end of the antenna failed to slide through the tubing. We now use antennas with continuous surfaces rather than ones with additional insulation at their ends.

Attachment to the first right or left costal prevented the transmitter from interfering with mating when males mounted females. We did not measure the effect of transmitters on tortoise behavior, but did observe several instances of males mounting females unobstructed by the transmitter and two transmittered animals successfully righting themselves after falling on their carapace.

Attaching the transmitter to the first right or left costal scute generally resulted in a fairly flush alignment with the top of the carapace, thus minimizing problems that could occur when tortoises with transmitters turn around inside their burrows. Three of our transmittered animals were found stuck in collapsed burrows following an unusually rainy winter, but we were unable to determine if the transmitters contributed to burrow collapse or tortoise entombment. None of three known mortalities of our transmittered animals were attributed to the presence of the transmitter (one was a road kill, one probably died from a respiratory disease, and one died of unknown causes).

Discussion.—Based on five years of observation, the method described herein successfully reduced loss of transmitters, increased transmission range, and prevented deformation of the shells, while minimally altering the animals' behavior. However, experiments designed explicitly to measure transmitter effect were not conducted.

Transmitter design is a three-way compromise between battery size, longevity, and transmission range (Brander and Cochran 1969; Macdonald and Amlaner 1980; Mech 1983). We found antenna orientation to affect transmission range. We found that transmission range was increased by allowing the antenna to lie across the top of the carapace. This orientation likely reduced nulls in the transmission signal caused by an open loop and reduced slightly ground attenuation (Mech 1983).

Allowing the transmitter and/or antenna to bind together two or more scutes may cause deformation of the shell as the animal grows. If the antennas were attached directly to the shell with epoxy, they would connect several scutes together for as long as the transmitter was attached; which may be the life of the animal if the animal becomes lost with the transmitter still attached. This would be particularly critical in rapidly growing turtles (e.g., hatchlings and juveniles). Although undocumented, shell deformations could be hazardous if they impede normal behavior or damage underlying tissues (B. Homer, pers. comm.).

We found that our transmittered tortoises were still able to mate apparently unimpeded by the transmitter and were able to successfully right themselves if tipped over during mating or aggression. Eckler et al. (1990) also observed the behavioral effect of attaching transmitters to 45 bog turtles (*Clemmys muhlenbergii*), and reported seeing successful foraging, mating, and nesting. They epoxied the transmitters to the fourth costal scute and attached the antennae directly to the carapace.

The method chosen for attaching radio transmitters depends on the size, behavior, potential future growth, and catchability of the species, as well as characteristics of the environment and the principal study objectives (e.g., length of study, type of data desired). It is essential that the transmitter not affect significantly the behavior, survival, or reproductive success of the study animals. Therefore, for relatively long-term applications (the length of time depends on the animal's growth rate, which depends in part on the animal's age), attachment should avoid causing shell deformation. Studies should be conducted to evaluate the effect that transmitters and their attachment methods have on turtles and tortoises with the results reported in the literature. Furthermore, studies using radio transmitters should provide sufficient detail on attachment methods to allow readers to evaluate the potential effect the transmitters may have on the animals and the study's results.

Acknowledgments.—We thank Marc Sazaki for his support and assistance with all aspects of this project. Paul Frank, Bill Clark, and Ray Romero assisted with the field work. Initial training on attaching transmitters to tortoises was provided by Mike Cornish and Chuck Peterson. Barbara and Quintin Kermeen, AVM Instruments Inc., provided invaluable assistance with transmitter design. Liz Lucke and Mary Jane Dodson of the Midcontinent Ecological Science Center assisted with the literature search. An earlier draft was reviewed by Sherry Barrett, Ken Dodd, Jr., Stan Ford, Whit Gibbons, Jeff Lovich, Don Moll, Kirk Waln, and an anonymous reviewer. The majority of funding was provided by the California Energy Commission, Bureau of Land Management, and National Biological Service, with additional support provided by Federal Highway Administration, Nevada Department of Transportation, California Department of Fish and Game, and California Department of Transportation. We refer to numerous trade-name items (denoted by *) in this manuscript to provide the reader with examples of equipment that works for this application. The use of any and all trade names in this paper does not imply endorsement by the federal government.

Increasing Lizard Capture Success Using Baited Glue Traps

MARTIN J. WHITING
Department of Zoology, University of Stellenbosch

**address for correspondence*

Bauer and Sadlier (1992) recently drew attention to the effectiveness of household glue traps for the sampling of herpetofauna, particularly lizards. Here I report on an experiment to test the effectiveness of baiting glue traps to capture the cordylid lizard *Platysaurus capensis*, as well as additional observations on sampling lizards with glue traps.

I used nontoxic Catchmaster® 9 x 12 cm Baited Mouse Glue Traps and to a lesser extent Catchmaster® 13 x 21 cm Baited Mouse, Insect & Snake Glue Boards (Atlantic Paste & Glue Co., Inc, 4-53rd Street, Brooklyn, New York 11232, USA) to sample *P. capensis* at Augrabies Falls National Park, South Africa (28°35' S, 20°20'E). The former trap is raised on a 9 mm plastic platform, the latter trap consists of flat, laminated cardboard. My field assistants and I have captured over 1000 *P. capensis* using glue traps. Since *P. capensis* inhabits rocky areas, glue traps were attached to rock using putty (Bostik®) to prevent lizards escaping with the trap. Traps were placed along crevices and across known activity corridors. In an attempt to increase capture success, I began baiting traps with brown unripened Namaqua figs (*Ficus cordata*) painted red to resemble ripe figs which were unavailable at the time of study, and which form part of *P. capensis*' diet (Whiting and Greeff 1997). To measure the effectiveness of this method, I baited 37 traps with a single red-painted fig (mean diameter of 40 figs: 6.17 ± 0.09 mm, Whiting and Greeff 1997) placed in the center of the trap. Thirty-seven unbaited traps served as controls. Baited and unbaited traps were placed in alternate sequence, during 28–29 August 1996 and continuously monitored. No lizard was caught more than once. Assuming an equal probability of capture as the null hypothesis, significantly ($\chi^2_1 = 23.14$, $P < 0.0001$) more lizards were caught on fig-baited (46 lizards) than control (10 lizards) traps. Also, significantly ($\chi^2_1 = 4.55$, $P < 0.05$) more lizards sampled (tongue-flicked) traps containing red-painted figs (16 lizards) compared to controls (6 lizards).

Platysaurus capensis were also attracted to traps baited with live, moving insects. In some cases lizards were caught after being chased onto a trap line they might otherwise have avoided. During the breeding season, males were often caught when they inspected trapped females.

In addition to *P. capensis*, geckos (*Pachydactylus* spp.) and the gerrhosaurid *Cordylosaurus subtessellatus* also were inadvertently caught. Also, during field work in Namibia, the subterranean gecko *Ptenopus garrulus* was captured by placing glue traps at the entrance to their burrows.

Bauer and Sadlier (*op. cit.*) suggested removing lizards from glue traps using corn oil. Lizards with relatively hardy integuments (such as *P. capensis*) may first be removed from a trap prior to the application of oil to remove excess glue. This greatly increases the longevity of the trap. Trap longevity can also be increased by avoiding windy situations or removing traps with the onset of wind.

This work supports Bauer and Sadlier's assertion that glue traps should be added to the arsenal of zoologists involved in herpetological sampling. In the case of autecological studies, especially for visually oriented species, capture success may be increased through trap baiting.

Acknowledgments—For assistance capturing *P. capensis* using glue traps at Augrabies Falls National Park, I am indebted to L. Bartman, P. W. Bateman, D. L. Bellars, S. Kirkman, S. V. Nelson, and L. Simpson. In Namibia, *P. garrulus* were captured during a field trip with W. E. Cooper, Jr. I thank N. H. G. Jacobsen for commenting on the manuscript.

A Simple Device to Prevent Small Vertebrate Animals from Drowning in Swimming Pools

MICHAEL J. TYLER
Department of Zoology, University of Adelaide
South Australia 5005, Australia

In many parts of the world small mammals, reptiles, and amphibians drown after falling into swimming pools, from which they are unable to escape. My attention was drawn to this matter following the discovery of a drowned pine marten, *Mustela martes,* in a pool at Toulouse, France, and of a live toad, *Bufo bufo,* in the skimmer box of the same pool. Here I describe the design of a simply constructed wooden raft now proven, from its use there, to have assisted the escape of such animals.

The device consists of two units comprising tongue and grooved wooden planks attached to a 4 x 4 x 50 cm square section wooden frame (Fig. 1). The two identical components are connected by a continuous brass hinge, permitting the ramp to adjust to changing water levels. The ramp is equipped with closely spaced bars to provide purchase for a creature leaving the water (Fig. 2). To minimize the angle at which the device touches the water, an empty plastic water bottle has been attached to the undersurface by means of a plastic strap (Fig. 1).

FIG. 1. Device in position: the right hand portion is placed directly above the skimmer box.

FIG. 2. Undersurface of device showing the framework upon which the boards are mounted, and the plastic water bottle in place.

The positioning of the device is vital to maximize access to trapped animals. The direction of pool water flow towards the skimmer box means that a weakened animal will float towards, and often into, the skimmer box where ultimately it will drown. The device was therefore placed over the skimmer box as shown in Fig. 2. Its first observed success, one week after its installation, was the emergence via the inclined ramp of a juvenile viper, *Vipera berus*.

HERPETOLOGICAL HUSBANDRY

A Safe, Single-Application Procedure for Eradicating Mites on Reptiles

**Author to whom all correspondence should be addressed.*

Mites are common ectoparasites that can cause serious health problems for squamate reptiles—particularly under captive conditions (Frye 1981; Lane and Mader 1996; Mader 1989; Marcus 1983). Mites can be difficult to extirpate completely (e.g., Mader 1989; Montanucci 1997), and as a result, numerous commercial products are now available to kill these pests (e.g., Abrahams 1992; Boyer and Boyer 1991). However, some of these products are unsatisfactory for one or more reasons, including toxicity, the need for veterinary direction, required changes in husbandry, high cost, or a lack of long-term efficacy (Mahaney 1995; Montanucci 1997).

Several non-commercial techniques have been described for eradicating mites from captive reptiles and their surroundings. One method traps mites by simply lining the perimeter of the animal's enclosure with masking tape (Mahaney 1995). Yet despite its ease of application, this method only removes dispersing individuals, and thus mites that remain in the substratum, on refugia in the enclosure, or on the animals themselves, will not be captured.

Recently, Montanucci (1997) described a procedure for eradicating mites by selectively removing the most critical stages of their life cycle—gravid females and egg cases. Although this method is reportedly effective, the process seems inordinately elaborate, and may require a substantial time investment. Specifically, this procedure includes a twice-weekly washing of the cage and refugia, and manual removal of gravid female mites and egg cases. Due to the lengthy life cycle of these pests, this process may ultimately take more than a month to eliminate an entire mite population (Montanucci 1997).

In our lab, we kill mites living on reptiles by immersing the reptiles in vegetable oil. The oil entraps and subsequently suffocates the mites by occluding their respiratory passages. This method offers the advantages of low cost and safety while completely eradicating the entire mite population with a single application. After several years of refinement, we have improved the efficacy of this method which is described below.

Unlike some methods (e.g., Mahaney 1995; Montanucci 1997), ours works by killing the mites that are on the animals. If one starts with a mite-free environment (see below), prevention of reinfestation is reduced to a process of killing mites on all new reptiles before they are introduced into established vivaria.

To eliminate mites from terraria, we have used a variety of mite-killing solutions including 70% isopropanol (rubbing alcohol), 10% bleach or ammonia, or dish or laundry detergent and hot water. The terrarium, and all non-living items that have come in contact with mites, are scrubbed and soaked for 5–10 min with one of these solutions, rinsed thoroughly, and air dried until no odors are detectable. Mites can also be removed or killed by spraying these items with the pressure from a garden hose (Montanucci 1997), but care should be taken to ensure that the treatment is thorough, because if critical areas are neglected (e.g., plastic frames of some aquaria, porous rocks, etc.), a reinfestation is likely to occur. For this reason, we generally dispose of the substratum (e.g., soil, sand, gravel, etc.) rather than attempting to disinfect and dry it.

To kill mites on reptiles, we thoroughly coat each animal with vegetable oil. In our experience, neither the type nor the brand of vegetable oil appears to affect the outcome. First, the animal is cooled to room temperature (ca. 20°C) to facilitate handling, then it is placed in a large container (e.g., a size-matched bowl, tub, or bucket) with enough oil to partially submerge the animal (i.e., one-third to one-half of the animal's height). We then use our hands to drip the oil liberally over the animal taking care to completely cover and massage the oil over all parts of the body (e.g., neck and body skin folds, joints of appendages, cloacal region, all parts of the head including the region surrounding the eyes). We have not witnessed any signs of distress from dripping the oil around the eyes, nares, or mouth. Highly infested animals, or those with large imbricate scales (e.g., desert spiny lizards, *Sceloporus magister*), are massaged in the oil for up to 1 min to ensure that the animal is thoroughly coated. The animals are then blotted with paper towels and held in a clean cage with a newspaper lining until the oily sheen on their scales diminishes (1–3 days). Water, heat sources, and refugia are provided, although we typically do not feed the animals during this time.

Reptiles that we have subjected to this treatment apparently are

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 28, Number 1 (March 1997).

CAUDATA

AMBYSTOMA TEXANUM (Smallmouth Salamander). **REPRODUCTION.** Salamanders were trapped from a temporary pond in Washington Township (T3S R10E NW1/4 Sec. 32), Hardin County, Ohio, USA between 1985 and 1995. On 14 March 1985 and 13 March 1995, salamander eggs were discovered hanging above the water from branches of buttonbushes (*Cephalanthus occidenatils*). We presumed these eggs were laid by *Ambystoma texanum* as this species represented 92% of all salamanders captured at this site. Additionally, these egg masses were similar to those known to be produced by *A. texanum.* Other salamanders encountered at this site were *A. tigrinum* (3%) and triploid/tetraploid ambystomid hybrids (5%). On 13 March 1995, 27 egg masses were laid in four buttonbushes, each 2–3 m high and clumped together in a 4 x 9 m area where the pond was ca. 50 cm deep. Branches were 1–2 cm thick and several had as many as 3 egg masses with 1–25 eggs/mass. Height of the egg masses above the water averaged 50 cm and ranged from 6–130 cm. During the morning of 14 March 1995, we observed 10 additional egg masses added to the branches above the water. All egg masses were desiccated by 15 March. Weather during the egg-laying episode in 1985 was light rain with sleet, air and water temperature was 14°C; during the 1995 period the skies were clear, air and water temperature was 11°C. In both years, rains preceding egg laying were not sufficient to raise the water level to the egg height. The landowner indicated he had not observed the water at this height during the preceding 25 years (A. G. Matson, pers. comm.). Without direct observation of the egg-laying process, it appeared that salamanders, probably *A. texanum,* climbed up the branches and laid eggs outside of their normal watery environment. We believe this is the first report of this unusual behavior.

Submitted by **NELSON J. MOORE**, Department of Biological Sciences, Ohio Northern University, Ada, Ohio 45810, USA, and **ARTHUR G. MATSON**, 7110 Country Road 60, Dola, Ohio 45835, USA.

PLETHODON KENTUCKI (Cumberland Plateau Woodland Salamander). **MORPHOLOGY.** Developmental aberrations that result in dicephaly often are reported in mammals (Siebert et al. 1989. Teratology 40:305–310; Camon et al. 1992. Anatomy and Embryology 185:45–56) and reptiles (Wallach 1995. Herpetol. Rev. 26:127–129). While the occurrence of twins in amphibian eggs has been noted (Lindberg 1995. Herpetol. Rev. 26:142), reports of dicephalic amphibians are rare. Here we document a dicephalic hatchling *Plethodon kentucki* from a clutch of 12 eggs deposited by a female collected at Big Black Mountain in Harlan County, Kentucky, USA (Marvin 1996. Am. Midl. Nat. 136:385–400). This dicephalic individual (ca. 14 mm SVL; similar in size to the other hatchlings) lived for several days after hatching, but was accidentally killed by overheating while being photographed. The left eye and lower jaw of the left head were misshapen, and the left head was slightly smaller than the right one (Fig. 1). A ventral view of the individual revealed the presence of two hearts. The preserved specimen was deposited in the University of Oklahoma Museum of Natural History (OMNH 34850). Eight of the remaining hatchlings appeared normal, whereas two exhibited kyphosis immediately behind the forelimbs and another's jaw was misshapen. The abnormal morphology of these four hatchlings is one of several cases of developmental abnormalities observed in *Plethodon* at this locality. Marvin (1995. Herpetol. Rev. 26:30) captured a juvenile *P. glutinosus* with extreme scoliosis (OMNH 34849), and another *P. glutinosus* with less severe scoliosis. The proportion of individuals observed in this area with developmental abnormalities was 0.65% (4/614) for *P. kentucki* and 1.68% (2/119) for *P. glutinosus.* These observations may indicate an unusual rate of developmental abnormalities for salamanders at this locality. We thank C. McCallister for photograph processing.

ANURA

CYCLORAMPHUS BORACEIENSIS (Flattened Waterfall Frog). **PREDATION**. On 22 December 1995 at ca. 1700 h in the Parque Estadual da Serra do Mar, Núcleo Picinguaba, Ubatuba, São Paulo, Brazil, we found a juvenile *Bothrops jararaca* (475 mm SVL) that contained an adult male *Cycloramphus boraceiensis* (40 mm SVL). This finding supports the hypothesis that the in-

guinal glands of *Cycloramphus* do not play an antipredatory role, at least with respect to *B. jararaca* (DeLucca et al. 1996. Braz. J. Morph. Sci. 13:15–19). Voucher specimens are in the Museu de História Natural da Universidade Estadual de Campinas (ZUEC 9701).

Submitted by **ARIOVALDO A. GIARETTA** and **RENATO NUNES**, Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas CP 6109, 13081-970 Campinas, Sao Paulo, Brazil.

LEPTODACTYLUS BOLIVIANUS (NCN). **BEHAVIOR.** Based on comparative morphology and behavior, Heyer (1969. Evol. 23:421–428) divided the genus *Leptodactylus* into four species groups. Females of *L. ocellatus* have been observed to actively protect the tadpoles by attacking a potential predator; Vaz-Ferreira and Gehrau (1975. Physis 34:1–14) found that females would strike a dead bird suspended on a pole above tadpole aggregations.

Currently, maternal attendance in *L. bolivianus* is not well understood. Wells and Bard (1988. J. Herpetol. 22:361–364) did not observe aggressive attacks in *L. bolivianus* as seen in *L. ocellatus* (Vaz-Ferreira and Gehrau, *op. cit.*), although they indicated that additional work might reveal this type of behavior. Herein, I report attack behavior observed from 13–18 July 1993 in three different females of *L. bolivianus* (mean SVL 79.2 ± 2.5 mm) in the same area studied by Wells and Bard (*op. cit.*). All females tested were guarding tadpoles in open water ca. 10 cm in depth. No changes were observed in tadpole behavior after the female's attack.

During my observations, made both day and night, a female attending a school of tadpoles would suddenly attack a meterstick that I was holding near her head. After the attack, the female returned to her original site 20 cm away. Subsequently, I presented each of three females with a rubber ball attached to a 40 cm stick. Two trials of 15 presentations each were made to each female. I moved the ball over the ground from a distance of 40 cm through the grass until it was 20 cm from the female, where it was held immobile for 1 min. I recorded the female's response (attack or escape). Five minutes later I began another test that was suspended if the female disappeared and did not return before the next five minutes. All three females displayed the same type of aggressive behavior. The frogs jumped from a distance of 30–40 cm away toward the ball, knocking it with their heads or pushing it with their hands. The females responded in the same manner to stimuli suspended over their heads.

Occasionally, females performed bouts of the pumping behavior described by Wells and Bard (*op. cit.*) prior to attacking the rubber ball. This behavior was highly variable among the females tested. I recorded 58 attacks of the model by the three females. Female 1 attacked 24 of 30 presentations with five attacks preceded by bouts of pumping behavior; Female 2 attacked 30 of 30 presentations with one bout; and Female 3 attacked 4 of 6 presentations with zero bouts. These results were obtained only during the nocturnal tests (2200–0100 h).

Females detected during the day were always completely hidden in the vegetation. Any attempt to present the rubber ball was followed by escape or no response. In contrast, females of *L. ocellatus* in Uruguay (Vaz-Ferreira and Gehrau, *op. cit.*), Goias, Brazil (J. Caldwell, pers. comm.), and Cordoba, Argentina (pers. obs.) attacked during the day.

This work was done while I was a short-term Fellow at the Smithsonian Tropical Research Institute (Panamá), which I gratefully acknowledge. Special thanks to J. Caldwell, who greatly improved the quality of this manuscript with suggestions and comments.

PSEUDACRIS OCULARIS (Little Grass Frog). **PREDATION.** At 11–17 mm SVL, *Pseudacris ocularis* is the smallest terrestrial vertebrate in North America (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co. Boston, Massachusetts. 450 pp). Numerous instances of invertebrate predation on anurans have been reported and spiders are among the known predators (McCormick and Polis 1982. Biol. Rev. 57:29–58). Herein we report an observation of a spider preying on an adult *P. ocularis.* This is the first report of predation on this species by a spider.

On the afternoon of 11 April 1992 at 1500 h in a cypress dome on the campus of the University of Central Florida (UCF), we encountered a gravid female *P. ocularis* (12.25 mm SVL) being held by an immature male wolf spider, *Lycosa* sp. Both were in a small depression ca. 3 cm deep and ca. 3 m from the water's edge. The initial attack was not observed; however, when the pair was first detected the spider had its fangs firmly embedded in the frog immediately posterior to the skull. Although the frog was still alive and struggled to free itself, the spider was in obvious control. After ca. 5 min of observation, both were collected and placed in the UCF vertebrate collection (UCF-21H). The spider maintained its grasp on the frog until placed in the preservative. Based on this observation as well as the small size of adults, we suggest that *P. ocularis* may be an important prey item for many species of vertebrates and invertebrates.

We thank G. B. Edwards of the Florida Department Agriculture and Consumer Services (Div. Plant Services) for identifying the spider.

RANA CURTIPES (Bicolored Frog). **REPRODUCTION.** *Rana curtipes* is commonly encountered in the Malnad region of western Ghats, particularly during the monsoon season, May–September. It is observed rarely during other times of the year and there is little information available on reproduction. Herein we report observations of amplexus in this species.

Rana curtipes initiates breeding during the later monsoon months (August–November). Three observations of mating behavior occurred in areas vegetated by ferns, grasses, and small bushes where the amplectant pairs were well concealed. Prominent sexually dimorphic characters visible during the breeding season include the development of two cream-colored spots on either side of the urostyle in the males. In addition, the urostyle of the females is slightly elevated distally. The vocal sacs are internal and vocalization is feeble, produced by the males only during the breeding season. The males are smaller than the females; males range from 30.2–65.0 mm (mean = 46.8 mm SVL; SD = 14.25 mm), whereas the females range from 40.4–80.0 mm (mean 56.8 mm SVL; SD = 16.87 mm). Amplexus was axillary in all observations. Initially, the forelimbs of the male were placed near the

shoulders of the female. However, as breeding proceeded the male achieved a posterior position and firmly gripped the female immediately behind the axilla. The thigh and shin of the male were placed parallel to the thigh and shin of the female, partly exposing the elevated urostyle of the female underneath the cloacal region of the male. Amplexus lasted for 1–4 days, during which time the males produced a characteristic call of "knu-knu-knu—" that lasted 2–80 sec. Females were observed to carry the males in this position to the aquatic breeding grounds. During such overland movements, the position of the hindlimbs of the male would be flexed and rested upon the thighs of the female. In one of three observations, oviposition occurred during darkness and lasted for 30 minutes.

We thank Richard A. Seigel and Charles W. Painter for their valuable comments on this manuscript.

SAURIA

AMEIVA CHRYSOLAEMA FICTA (NCN). **PARASITISM.** *Ameiva chrysolaema ficta* is a moderately large (males to ca. 120 mm SVL) ground-dwelling lizard found in xeric habitats of the lower Península de Barahona of Hispaniola (Schwartz and Klinikowski. 1966. Bull. Mus. Comp. Zool. 133:425–487; Schwartz and Henderson. 1991. Amphibians and Reptiles of the West Indies. Univ. Florida Press; Schell et al. 1993. Cat. Amer. Amphib. Rept. 563:1–6). Lizards were collected during June 1995 in *Acacia* scrub 4.5 km NW Oviedo, Provincia de Pedernales, República Dominicana. A single nematode, 4.5 mm in length, was found encysted in the peritoneum of a subadult male (80 mm SVL) collected 4 June 1995 and was identified using scanning electron microscopy as an immature anisakine ascarid, *Terranova* sp., probably *T. caballeroi*. The lizard most likely served as a paratenic or intermediate host for the nematode, adults of which should occur in a predator of the lizard, most likely one or more species of snake. Powell et al. (1990. Carib. J. Sci. 26:72) found adult parasites in *Antillophis parvifrons protenus*, a known predator of *Ameiva* (Henderson et al. 1987. J. Herpetol. 21:330–334). Only one of 37 *A. chrysolaema ficta* was infected, and no parasites were found in 25 *A. leberi* or 40 *A. taeniura vulcanalis* collected in the same area during the same period.

Birt et al. (Herpetol. Rev., in press) found larval *Terranova*, similar to those of *T. caballeroi*, in *Anolis barkeri* from México and summarized the literature dealing with terrestrial *Terranova* in squamates.

Richard E. Glor, Laurel M. Hartley, Ellen J. Censky, John S. Parmerlee, Jr., and Andrew H. Price helped in the field. Permits were issued by Lic. Geraldino Caminero M.Sc., Director, Departamento de Vida Silvestre. Field work was funded by NSF Grant no. BIR-9224486 awarded to RP.

GREVE**, Department of Veterinary Pathology, Iowa State University, Ames, Iowa 50011, USA, and **ROBERT POWELL**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145, USA. *Present address: Department of Systematics and Ecology and Natural History Museum, University of Kansas, Lawrence, Kansas 66045, USA.

ANOLIS BARKERI (Barker's Anole). **PARASITISM.** *Anolis barkeri* is a moderately large (male SVL ≤ 100 mm) anole with distinctly aquatic habits and an opportunistic feeding strategy (Brandon et al. 1966. Herpetologica 22:156–157; Kennedy. 1965. Zoologica [N.Y.] 50:41–43; Meyer. 1968. Copeia 1968:89–95; Meyer. 1968. Bull. So. California Acad. Sci. 67:255–262; Robinson. 1962. Copeia 1962:640–642). Specimens were collected along a permanent stream above Lago Escondido near the Estación Biología "Los Tuxtlas" in southern Veracruz, México. Although most lizards were released after marking, ten individuals died or were killed and dissected; all were deposited in the collection at the station (UNAM–LT, numbers not assigned at this time). Six small nematodes, 3.50–3.75 mm in length, were found encysted in the peritoneum of a juvenile female (34.4 mm SVL) collected 22 June 1996 and were identified using scanning electron microscopy as immature anisakine ascarids, probably *Terranova* sp. The anole most likely served as a paratenic host for these nematodes, adults of which should occur in a predator of the lizard, most likely one or more species of snake. Barus and Coy Otero (1966. Poeyana, ser. A [23]:1–16) described *T. caballeroi* from Cuban *Alsophis cantherigerus pepei*. Collins (1969. J. Elisha Mitchell Sci. Soc. 85:141–144), Sprent (1979. J. Helminthol. 53:265–282), and Camp (1980. Proc. Helminthol. Soc. Washington 47:276–277) recorded this nematode in *Agkistrodon piscivorus piscivorus*, *Coluber constrictor*, *Heterodon platirhinos*, and several species of *Nerodia* from the southeastern United States. Powell et al. (1990. Carib. J. Sci. 26:72) found adult parasites in *Antillophis parvifrons protenus* from Hispaniola. The nematodes in *Anolis barkeri* may be juvenile *T. caballeroi*, although the cecum is shorter than ceca from *Terranova* larvae that are more probably *T. caballeroi* from Hispaniola. Regardless of specific status, these nematodes from México represent new host and geographic records.

ANOLIS PENTAPRION (Lichen Anole). **FRUGIVORY and CANNIBALISM.** The diet of this species was analyed from a large population at San Rafael, a disturbed area of some 20 ha near Santa Rosa Cintepec (municipality of Catemaco), Veracruz, México (400 m).

The local habitat has undergone significant alteration in recent years, including the cultivation of an introduced shrub, grosella (*Eugenia uniflora* of the family Myrtaceae). During the warm rainy season (May–September), the shrub produces a small, red, bland but juicy fruit that is prized for human consumption. *Anolis pentaprion* has taken to eating the mature grosella fruit. Six stomach contents of 20 adult *A. pentaprion* contained the remains and seeds of grosella fruit. Small lizards (hatchling *A. pentaprion*) were also present in four stomachs, and arthropods (principally insects) occurred in almost all of the rest. These observations confirm a cannibalistic habit, as well as a facultative omnivory.

We are indebted to Biol. Alvaro Campos Villanueva for identification of plant material.

Submitted by **GONZALO PEREZ-HIGAREDA**, Estación de Biologia Tropical "Los Tuxtlas," Apartado Postal 51, Catemaco, Veracruz, México; and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

BARISIA IMBRICATA PLANIFRONS (Oaxacan Imbricate Alligator Lizard). ANTIPREDATOR BEHAVIOR. The anguid lizard *Barisia imbricata* is distributed in the mountainous regions of northern and central Mexico. It is subdivided into four subspecies, with the subspecies occurring in central and southern Oaxaca assigned to *planifrons* (Guillette and Smith 1982, Trans. Kansas Acad. Sci. 85(1): 13–33).

On 24 July 1994 an adult male *Barisia imbricata planifrons* was caught on Cerro San Felipe just north of the city of Oaxaca, 2200 m elevation. As it attempted to hide in the forest litter it had to be extracted with some force, eliciting the following behavior. Immediately after capture it curled into a loop, attempting to hide the head under the tail. At the same time the hemipenes were everted. After attaining this posture the lizard remained completely motionless. Even leaving it on the forest floor did not put the lizard at ease, and as it did not "uncurl" after being watched for about 15 minutes, it was left in peace.

In order of occurrence, the following phenotypic categories, as defined by Greene (1988. *In* Gans and Huey (eds.), Biology of the Reptilia, Vol. 16, Ecology B. pp. 1–152. Academic Press, New York), could be recognized: 1) locomotor escape (attempting to avoid capture by hiding in forest litter); 2) head hide (by attaining a loop posture, the head was hidden under the tail); and 3) eversion of hemipenes.

Locomotor escape is a common phenomenon in most lizards. The loop posture has been observed in different gerrhonotine lizards, e.g., *Elgaria multicarinata* (Compton 1933, Copeia 1933(4):225; Fitch 1935, Trans. Acad. Sci. St. Louis 29(1):1–38) and *Elgaria kingi* (Bowker 1987, Herpetol. Rev. 18(4):73, 75). In both species the loop posture was accompanied by a bite to either the tail or one of the extremities. This was not observed in *Barisia imbricata*.

I thank Fernando M. Quijano (UNAM) for help in identifying the lizard.

FIG. 1. Male *Barisia imbricata planifrons* in loop posture hiding its head under the tail.

EMOIA CAERULEOCAUDA (Pacific Blue-tailed Skink). **CAPTIVE REPRODUCTION**. Information on life history attributes of *Emoia caeruleocauda* from the Mariana Islands is limited. McCoid (1994. Herpetol. Rev. 25:98–100) reported on egg, clutch, and hatchling size. Herein we present additional information on hatchling size, incubation period, size at maturity, and reproductive periodicity based on a captive sample.

In July 1995, 10 *E. caeruleocauda* were collected on Guam, Mariana Islands, and shipped to Kingsville, Texas. Initially, the group of 10 was divided between two 20 gallon aquaria, but all lizards repeatedly fought and there were five fatalities. In February 1996 the four surviving adults and a large female juvenile were placed in three 10 gallon aquaria and divided into two male-female pairs and a single adult male. Each aquarium had a sand substrate, water dish, potted ivy plant, two flattened rocks for cover, and a plastic hide box filled with soil. Lizards were maintained on a 12h:12h light:dark schedule via UV emitting fluorescent bulbs set in aquarium reflectors and given water and food (live crickets) ad libitum. Temperatures and humidity varied daily between 24°–33°C (although a hot spot for basking exceeding 50°C was created in each tank with the use of broad spectrum 50 watt heat lamps) and 70%–92%, respectively. These weather parameters resemble daily diurnal ranges on Guam (Anonymous 1990. NOAA Natl. Clim. Data Center, Asheville, North Carolina. 8 pp.).

Between July 1995 and February 1996, four clutches were deposited in the two tanks but we were unable to discern which females deposited clutches. In early February 1996, the two separated females began laying eggs. From February through July 1996, 12 clutches were deposited (five in one tank and seven in the other). In the tank with five clutches, time between clutches was 24–29 days (mean 26.75) and in the seven clutch tank, time between clutches was 28–35 days (mean 31.75). We observed an invariant clutch size of two (McCoid 1994. *op. cit.*) and an incubation period of 40–42 days. All clutches produced at least one viable egg. Hatchlings were slightly larger (mean SVL 23.4 mm, N = 5) than those reported by McCoid (1994. *op. cit.*).

Size at sexual maturity in female *E. caeruleocauda* has been estimated as ca. 43 mm SVL (McCoid 1989. Job Progress Rep. E-1-4. Div. Aquatic Wildl. Res., Gov. Guam. 45 pp.). We measured the maturing female mentioned above as depositing her first clutch of eggs at 45.9 mm SVL.

GECKONIA CHAZALIAE (Helmeted Gecko). **MAXIMUM SIZE**. During a recent project devoted to Mauritanian littoral biodiversity (C.C.E., "Projet Biodiversité du Littoral Mauritanien" –1993/1995), important herpetological collections and observations were made on the entire coast of Mauritania (Ineich et al., in prep.). Among these, six adult specimens of *Geckonia chazaliae*

were collected during the day and night at Cap Blanc on 14 May 1995 (21°07'97/100N, 16°57'45/100W) and deposited at the Paris Natural History Museum (MNHN 1996.6267–6271, 1996.6385; 3 males and 3 females).

One female (MNHN 1996.6270) was remarkable by its snout-vent length of 74 mm, exceeding by 10 mm the maximum known (Schleich et al. 1996, Amphibians and Reptiles of North Africa, Koeltz Scientific Publ., 630 pp.). The maximum width of its body was 27 mm. It was collected around 1500 h under a stone. It was kept in captivity for several months by one of us (FG), and laid eggs four times (2 eggs, 1 egg, 2 eggs, and 1 egg) from June 1995 to January 1996. Egg size varied from 7–12 x 12–15 mm.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). **INTRASPECIFIC INTERACTIONS**. The edificarian *Hemidactylus turcicus* has been established in south Texas, USA, for at least 45 years (Conant 1955. Amer. Mus. Novit. 1726:1–6) and has since spread north and west throughout the state. We report on a population of *H. turcicus* from the Rio Grande Valley, located on a house and in an RV park 3.2 km E Edinburg, Hidalgo Co., Texas. Data are presented on tail-break frequencies, sex ratio, and certain behaviors. Specimens were externally sexed by the presence of pre-anal pores on males (Selcer 1986. Copeia 1986:956–962), preserved in 10% formalin, and will eventually be deposited in the TCWC.

Selcer (1987. J. Herpetol. 21:74–78) reported males fighting over insects with resultant body scars and missing tails and toes, but did not record tail-break rates of either sex. To the best of our knowledge, tail-break frequencies have not been published for any population of *H. turcicus*. During a study to determine recolonization rates, we hand collected 53 geckos (2200–2400 h) on 25 June 1994 from the study site. Care was taken not to damage geckos during collection and natural tail-break frequencies were accurately recorded. Males (N = 17) had a 41.2% tail-break frequency and females (N = 34) a 35.3% frequency. Tail-break frequencies between sexes were compared using a c^2 test and were not statistically different ($0.9 < p < 0.5$). Pooled tail-break frequency was 35.8%. During confinement, prior to preservation, it was noted that many geckos would spontaneously autotomize tails, suggesting that examination of museum specimens may lead to inflated estimates of tail-break rates.

Between April 1992 and December 1992, we frequently observed, from a distance ≤ 1 m, *H. turcicus* forage on windows and screens at the south Texas study site. Geckos (N = 2–5) on any given window were usually of both sexes and approaches between individuals during feeding were routinely as close as 1 cm. At no time were any agonistic encounters observed or any vocalizations heard. In a recent study (Vaughan et al. 1996. J. Herpetol. 30:46–51) involving competition for perch sites between *H. turcicus* and *Crytopodion scabrum*, no vocalizations, either in mixed species or single species enclosures, were heard or aggressive interactions observed (R. Vaughan, pers. comm.). Marcellini (1977. Amer. Zool. 17:251–260) and Frankenberg and Marcellini (1990. Isr. J. Zool. 37:107–118) described agonistic displays and vocalizations of *H. turcicus* during intraspecific encounters. If vocalizations, as suggested by Marcellini (1977, *op. cit.*), are normally associated with intraspecific interactions and territoriality, then levels of intraspecific aggression may be low in some Texas populations. Additional observations support this conclusion. Geckos normally foraged beneath lights at the study site. At three specific collecting points (Base plates I–III) in the trailer park, 5–8 adult geckos of both sexes were clustered around lights attached to a 155 cm^2 metal base plate mounted to the wall. During the day, space beneath these base plates served as diurnal refugia for those geckos that foraged around the light at night. At these sites and other known diurnal refugia, geckos were observed diurnally in quiescent contact in these communal situations. Other species of arboreal geckos with which we are familiar (*H. frenatus, Lepidodactylus lugubris, Gehyra mutilata, G. oceanica*, and *Perochirus ateles*) are solitary in diurnal refugia. These observations suggest that, comparatively, *H. turcicus* is relatively gregarious and may display low levels of intraspecific aggression.

Sex ratio in our sample was biased in favor of females (1:2). Selcer (1986, *op. cit.*) reported a balanced (1:1) sex ratio, but his sample size was considerably larger. Of our 53 specimens (mean snout–vent length (SVL) = 49.8 mm, SD = 7.4), we scored only the two smallest (23.4 and 25.2 mm SVL) as juveniles. Only juveniles were collected on the ground while all others were collected generally under lights from sides of buildings at heights of 0.1–3.0 m.

We thank Eric Moum and David Hensley for assistance in the field and Rosemary Hensley for logistic support at the study site. A draft of this manuscript was reviewed by James R. Dixon, Robert Powell, and Andy Holycross. We also thank Walter Meshaka, Paul Klawinski, Oscar Flores-Villela, Kathryn Vaughan, and Kyle Selcer for sharing information.

IGUANA IGUANA (Green Iguana). **LONGEVITY.** There has been a tremendous increase in knowledge of care and culture of green iguanas in the past 20 years. Yet, to my knowledge, there are few (or no) longevity records for this species (Burghardt and Rand, eds.,1982, Iguanas of the World, Noyes Publ, Park Ridge, New Jersey, 472 pp.; Frye 1995, *Iguana iguana*: Guide for Successful Captive Care, Krieger Publ. Co. Malabar, Florida). The purpose of this note is to establish one such record. A female iguana was purchased as a hatchling from a pet shop early in 1968. She died 14 January 1996, at an age of nearly 28 yrs. At her death, her SVL was 432 mm, her head was 103 mm long, and she weighed 1792 g.

Submitted by **KAREL L. ROGERS**, Biology Department, Grand Valley State University, Allendale, Michigan 49401-9403, USA. E-mail: rogersk@gvsu.edu.

LACERTA AGILIS (Sand Lizard). **DERMATOPHAGY.** *Lacerta agilis* is the most common lizard in the Czech Republic, and it inhabits a variety of habitats including manmade structures in urban environments. In 1994 a survey of the diet of *L. agilis* was conducted as part of a wider ecological study (Gvozdík 1995.

A Contribution to Ecology and Morphometry of Sand Lizard, *Lacerta agilis* Linnaeus, 1758. Unpubl. M.S. Thesis, Palacky Univ., Olomouc.[in Czech]) near a river embankment in the town of Opava, Opava County, Czech Republic (49°56'N, 17°54'E, elev. 250 m). On 14 August 1994 an adult male *L. agilis* (65.5 mm SVL) was captured with a portion of its shed skin attached to the posterior part of the body. The stomach contents were obtained by stomach flushing (James 1990. Herpetol. Rev. 21:87–88) and were preserved in 10% formalin. The stomach content analysis did not reveal any invertebrate prey items, but several pieces of lizard skin were found. Because shed skin occurred on the lizard's body and in its stomach simultaneously, it is probable that the shed skin was consumed as a deliberate act, rather than being ingested during aggressive, mating, or other activities with a conspecific (Weldon et al. 1993. J. Herpetol. 27:219–228). This report is in contrast to the comprehensive study by Lukina (1976. *In* A. V. Jablokov, ed., Sand Lizard, pp. 179–213. Nauka, Moscow. [in Russian]), who did not record skin in the contents of 3945 stomachs of *L. agilis*.

SCELOPORUS JARROVII (Yarrow's Spiny Lizard). **REPRODUCTION IN MEXICO.** Although the reproductive biology of *S. jarrovii* has been studied in the United States (Goldberg 1971. Herpetologica 27:123–131; Ballinger 1973. Ecology 54:269–283), there are, to my knowledge, no published accounts of its reproduction in Mexico. In this note I report on an examination of gonads from 19 *S. jarrovii* from Morelos, Mexico. Specimens were examined from the Texas Cooperative Wildlife Collection (TCWC): 3824–3826, 3828–3830, 3832–3838, 3841, 6873–6877. Except for TCWC 3824, which was from Lagunas de Zempoala (19°05'N, 99°19'W; ca. 3050 m elev.), 8 August 1950, all others were from 3 km W Huitzilac, (19°03'N, 99°15'W; ca. 3050 m elev.) and were collected 26–31 July 1949 (TCWC 3825–3826, 3828–3830, 3832–3833, 3834–3838, 3838, 3841) or 8 August 1950 (TCWC 6873–6875, 6877). The left gonad was removed and embedded in paraffin for histological examination. Sections of testes were cut at 5 µm and stained with hematoxylin and eosin counterstain. Gross observations were made of ovaries. The female sample (N = 4) had a mean snout–vent length (SVL) of 65.3 mm ± 3.2 SD (range = 62–68); male sample (N = 15) mean SVL = 81.6 mm ± 7.4 SD (range = 71–93). All lizards were reproductively active. Testes were undergoing spermiogenesis; lumina of seminiferous tubules were lined by sperm and several rows of metamorphosing spermatids were present. Each of the 4 females were reproductively active: TCWC 6875 contained 4 oviductal eggs; TCWC 3824 contained 5 enlarged eggs measuring 6 mm diam; TCWC 6877 contained 2 enlarged eggs measuring 4 mm diam; TCWC 3834 contained 3 enlarged eggs measuring 3 mm diam. These observations contrast with those of Goldberg (1971) who found male *S. jarrovii* from the Baboquivari (= Quinlan) Mountains (31°95'N, 111°59'W; 1920 m elev.) Pima County, Arizona, USA (ca. 1870 km N of the Morelos population) did not begin spermiogenesis until September; females did not accumulate yolk until autumn with ovulation occurring in mid-November to early December. Similarly Ballinger (*op. cit.*) found male *S. jarrovii* collected in August from the Chiricahua Mountains, Cochise County, Arizona, contained neither spermatids nor spermatozoa. Clearly, the *S. jarrovii* reproductive cycle is accelerated in Morelos when compared to that of *S. jarrovii* in southeastern Arizona. It is conceivable that this acceleration is because of a shortened activity season resulting from a colder climate in the high elevation habitat (3050 m) of the Morelos population. In any case, my observations have indicated significant variation in timing of the reproductive cycle between populations of *S. jarrovii* in different parts of its range.

I thank James R. Dixon and Kathryn Vaughan (Texas A & M University) for permission to examine *Sceloporus jarrovii*, and Robert L. Bezy (Natural History Museum of Los Angeles County) for taxonomic verification.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA.

TROPIDURUS MELANOPLEURUS (NCN). **PARASITES.** *Tropidurus melanopleurus* is a tropidurid lizard found on the eastern slopes of the Andes from Argentina to Perú. Captures of some individuals for an ecological study of this species (see Pérez-Mellado and de la Riva 1993. Copeia 1993:969–976) led me to examine the digestive tract of 36 lizards for parasites from which three helminth species were found: *Parapharyngodon sceleratus* (Travassos, 1923) (Nematoda: Oxyuroidea: Pharyngodonidae) from the cloaca, *Strongyluris oscari* Travassos, 1923 (Nematoda: Heterakoidea: Heterakidae) from the gut, and *Physaloptera retusa* Rudolphi, 1819 (Nematoda: Physalopteroidea: Physalopteridae) from the stomach and gut.

This is the first helminthological record for *T. melanopleurus* as a host for the helminths mentioned above. Nevertheless, these nematodes are common species of the neotropical helminth fauna and have been recorded from other species of *Tropidurus* and from other reptile hosts (Barus 1973. Folia Parasitol. 20:131–139; Masi-Pallarés et al. 1973. Rev. Parag. Microb. 8:67–113; Pereira 1935. Arch. Inst. Biol. Rio de Janeiro 6:5–27; Vicente 1981. Atas Soc. Biol. Rio de Janeiro 22:7–18; Vicente and Santos 1967. Atas Soc. Biol. Rio de Janeiro 11:75–77).

Global prevalence (percentage of parasitized lizards in relation to sampled lizards) is 66.7%, similar to the near 67% of *T. torquatus* and *T. spinulosus*, (Vicente 1981. Atas. Soc. Biol. Rio de Janeiro 22:7–18). There were no differences between males and females with regard to infestation prevalence (68.8% in males; 65% in females). Among the parasite species, *P. retusa* was the most prevalent species (53% of the lizards parasitized), *P. sceleratus* 25%, and *S. oscari* 14%. The mean intensities of infestation (mean total number of specimens of each parasite species in relation with the number of hosts parasitized by that parasite) were 4.4 for *S. oscari*, 3.3 for *P. sceleratus*, and 2.4 for *P. retusa*.

I thank Valentín Pérez-Mellado and Ignacio de la Riva for permitting the helminthological analysis of the digestive tract of the lizards.

TUPINAMBIS MERIANAE (Common Tegu). **PREDATION.** Verified reports of predation on *Tupinambis* species by predators other than humans are rare. Juvenile *T. teguixin* were reported in the diet of gray hawks (Haverschmidt. 1968. Birds of Surinam: I–XXIX. Edinburgh and London), and Gudynas wrote, "There are no known predators of *Tupinambis teguixin* in Uruguay except for man and his dogs." (Gudynas 1981. Bull. Chicago Her-

petol. Soc 16[2]:29–39). On 10 October 1996, on a dirt road near the Jejui Mi headquarters of Mbaracayu Reserve, Canindeyu, Paraguay (24°15'S, 55°32'W), we (RP and LAF) found the remains of an adult *T. merianae* regurgitated by a large cat. Based on the size of scales, feet, and its large jowls, the specimen was an adult male, > 350 mm snout–vent length. Four Ache Indians, who use the reserve as their traditional hunting gounds and are themselves important predators of *Tupinambis merianae,* verified the large pieces of *Tupinambis* skin and bone fragments, mixed with fresh grass leaves, as being regurgitated by either a jaguar (*Panthera onca*), or a puma (*Puma concolor*). Though both jaguar and puma occur in the reserve, jaguar are encountered at much higher rates along standardized biodiversity transects in the semideciduous Atlantic rainforest characteristic of Mbaracayu (Hill, in press. Cons. Biol.). On 23 October 1993, also at Mbaracayu Reserve, RV found scat of a jaguar containing the remains of an adult *T. merianae.* These are the first reports of predation on *Tupinambis* by large felids.

SERPENTES

BOTHROPS ALTERNATUS (Vibora de la Cruz). **REPRODUCTION**. Little is known about reproduction of *Bothrops alternatus* in Argentina. On 15 January 1995 I captured a gravid female (1110 mm SVL, 1220 mm total length) 65 km NE Villa Minetti (8 km NE of Centro Educativo Rural Nro. 249), Departamento 9 de Julio, Provincia de Santa Fe, Argentina. The environment where the specimen was collected is a flooded salt meadow ("bajos submeridionales de Santa Fe" [Lewis and Pire 1981. Ser. Fitogeog. INTA 18:22–31]) characterized by the lack of arboreal structure. "Espartillares" (*Spartina argentinensis*) is found in dense islands of 1.5 m in height; in one of these the snake was found with several specimens of *Mabuya dorsivittata* (Scincidae) and *Leptodactylus gracilis* (Leptodactylidae). Dissection revealed 26 embryos (14 in right oviduct, 12 in left oviduct); 14 males (with everted hemipenes) and 12 females (mean male SVL = 217.3 mm; mean female SVL = 251.5 mm). Previously published clutch sizes for *B. alternatus* include 10–18 (Cei 1993, Reptiles del Noroeste, Nordeste y Este de la Argentina, Mon. XIV, 929 pp.), 16 (Orrego-Aravena 1971, Rept. La Pampa, Bib. Pam. Ser. Foll. 14), and 20–30 (Vaz-Ferreyra et. al. 1980, Rel. Prog. y Cria Rept. R.O.U., Res. Jor. C. Nat. 1: 121–122; Miranda et. al. 1983, Guia Of. Bon., Asoc. Coop. Zool. La Plata). The specimen (ZV-UNRC 3610) was deposited in the herpetological collection of the Orintación Zoologia Vertebrados of the Universidad Nacional de Río Cuarto, Río, Río Cuarto, Argentina

Submitted by **LISANDRO CARDINALE**, Departamento de Ciencias Naturales, Universidade Nacional de Río Cuarto, 5800 Río Cuarto, Córdoba, Argentina and **LUCIANO JAVIER AVILA**, CONICET - Departamento de Ciencias Naturales, Universidad Nacional de Río Cuarto, Córdoba, Argentina.

CROTALUS PRICEI (Twin-spotted Rattlesnake). **REPRODUCTION.** On 24 July 1995, a female *Crotalus pricei* was collected from the Barfoot talus slide in the Chiricahua Mountains, Cochise Co., Arizona. The snake was brought to the Arizona-Sonora Desert Museum and housed in an individual vivarium, where she was offered water but no food. Between 1330–1500 h on 4 August 1995, the female (SVL 499 mm, tail length 35 mm, capture mass unknown) gave birth to 7 neonates (2 male:5 female). The neonates were weighed immediately upon discovery; their mass ranged from 5.5–6.4 g (mean ± SD = 5.73 ± 0.31). The combined mass of the seven neonates was 53% of the 76.3 g postpartum mass of the female. The size of this litter is within the published range (3–9), but the neonates were heavier than for previous reports (range 2.4–5.6 g) (Armstrong and Murphy 1979. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 88 pp; Lowe et al. 1986. The Venomous Reptiles of Arizona. Arizona Game and Fish Department, Phoenix, 115 pp.; Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. 2nd ed., Houghton Mifflin Company, Boston, Massachusetts, 336 pp.).

I thank Dennis Caldwell for assistance in the field work and William Altimari for comments on this manuscript.

Submitted by **PATRICIA A. MAHANEY,** Arizona-Sonora Desert Museum, 2021 North Kinney Road, Tucson, Arizona 85743, USA.

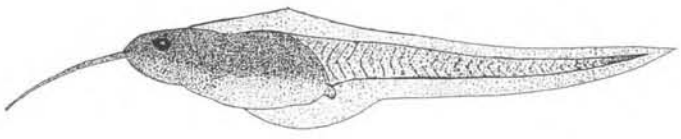
HYPSIGLENA TORQUATA JANI (Texas Night Snake). **MAXIMUM SIZE**. Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.) list the maximum size of *Hypsiglena torquata jani* as 508 mm total length (TL). On 16 May 1996, an adult female measuring 615 mm TL and 530 mm SVL was taken from Lajitas, Brewster Co., Texas, USA (UTM coordinates 13 618865E 3237654N). This individual represents a new record for maximum size for this taxon. The specimen has been deposited in the Museum of Texas Tech University (TTU 11623).

Submitted by **FRANKLIN D. YANCEY, II**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

PITUOPHIS MELANOLEUCUS ANNECTENS (San Diego Gopher Snake) and ***MASTICOPHIS LATERALIS LATERALIS*** (California Striped Racer). **PREDATION**. At 1021 h on 3 September 1996, while driving on the Santa Rosa Plateau Reserve, Riverside County, California, USA, I observed an adult male American kestrel (*Falco sparverius*) fly from a fence post with a snake in its talons. The kestrel alighted next to the road on a wooden bird nesting box and proceeded to eat the snake. I examined the snake through binoculars and identified it as a juvenile (ca. 350 mm total length) *Pituophis melanoleucus annectens*. At 1030 h on 20 September 1996, while riding on Camp Joseph H. Pendleton Marine Corps Base, San Diego County, California, USA, six of us observed a male American kestrel alight from next to the road with a juvenile (ca. 350 mm total length) *Masticophis lateralis lateralis* in its talons.

Although American kestrels are known to prey upon a wide variety of insects, small mammals, birds, and lizards (May 1935. The Hawks of North America. The National Association of Audubon Societies, New York. 140 pp.), only Dawson (1923. The Birds of California. Vol. 4. South Moulton Company, San Diego. pp. 1549–2121) records them taking "small snakes...as occasion offers." These are apparently the first records of American kestrels preying on gopher snakes and striped racers.

My thanks to Galen B. Rathbun and Scott B. Terrill for reviewing the manuscript. The Nature Conservancy graciously allowed the use of facilities on the Santa Rosa Plateau Reserve and the United States Marine Corps granted permission to conduct herpetological observations on Camp Joseph H. Pendelton.



Submitted by **MARK R. JENNINGS**, National Biological Service, California Science Center, Piedras Blancas Research Station, P.O. Box 70, San Simeon, California 93452-0070, USA, and Research Associate, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-9961, USA.

TRIMORPHODON BISCUTATUS QUADRUPLEX (Lyre Snake). **DIET.** Diet records from wild *Trimorphodon biscutatus* include lizards and small mammals (including bats), but captive specimens also accept amphibians and birds (Scott and McDiarmid 1984. Cat. Am. Amph. Rept. 353:1–4). Here I report a bird in the diet of a wild-caught individual. On 26 August 1996 at 0950 h, a male *T. biscutatus* (1150 mm SVL, 1400 mm TL, 360 g including prey) with a pronounced prey bulge was observed in the rafters of an unused ranger station at Puerto Chamorro, next to the Rio Tempisque in Palo Verde National Park, Guanacaste District, Costa Rica. The snake was captured and a groove-billed ani (*Crotophaga sulcirostris*, Cuculiformes) was removed from its stomach. The bird had been ingested headfirst, weighed 55 g, and was a fledgling (molting into juvenile plumage with all flight feathers less than 75% adult size).

A large female *T. biscutatus* (1380 mm SVL, 1635 mm TL, 450 g, with opaque eyes indicating pre-shed conditions) was found 2 m from the above-mentioned male, also in the rafters of the ranger station. A number of juvenile *Ctenosaura similis* (spiny-tailed iguanas) were observed around the station's roof tiles and surrounding trees, and numerous groove-billed anis and orange-fronted parakeets (*Aratinga canicularis*) landed on the roof during a one-hour observation period. Prey thus appeared to be spatially predictable and in high abundance for the snakes.

I thank the Organization for Tropical Studies for providing field accommodations and logistic assistance, and the Costa Rican Ministerio del Ambiente y Energia (Sistema Nacional de Areas de Conservacion) for a research permit.

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: LOUISIANA: Calcasieu Parish: Lake Charles, McNeese State University campus. 13 July 1997. Avery A. Williams and Mark L. Wygoda. Seale Museum of Louisiana, McNeese State University (SML 9313). Verified by Jeff Boundy. First parish record, and the only known record in the state outside of the New Orleans area as mapped by Dundee and Rossman (1989 The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge. 300 pp.). This specimen, a gravid female, was collected from an area landscaped with jasmine (*Trachelospermum* sp.) on the south side of the Student Union Annex building. Males of this species were initially heard calling from the collection site on 21 May 1997.

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA, and **MARK L. WYGODA**, Department of Biological and Environmental Sciences, McNeese State University, Lake Charles, Louisiana 70609, USA.

HYLA ORNATISSIMA. VENEZUELA: BOLIVAR: Salto Karuay, 23 km W Kavanayen, Sector Oriental del Pargue Nacional Canaima (5°40'N, 61°50'W). 900 m elev. 5–8 August 1996. J. Celsa Señaris and Oswaldo Vernet. Museo de Historia Natural La Salle (MHNLS 13377, 13382–85, 13401–02, and 133403). Verified by José Ayarzagüena. First record for Venezuela and a significant increase in the elevation range of the species. All specimens (seven males and one female) were collected at night between 1900 and 2100 h on a small bank of the river where the gallery forest was more open.

Submitted by **JOSEFA CELSA SEÑARIS** and **OSWALDO VERNET**, Department of Herpetology, Museo de Historia Natural La Salle, Apartado 1930, Caracas 1010-A, Venezuela.

HYLA VERSICOLOR (Gray Treefrog). USA: ILLINOIS: Scott Co: DOR on Hillview-Eldred Road, 0.3 km N Sandy Creek, Sec. 23, T13N, R13W. 5 April 1997. J. K. Tucker. Illinois Natural History Survey (INHS 12956). Verified by C. A. Phillips. New county record. Only *Hyla versicolor* (slow call type) were heard calling from chorus bordering roadside at this location.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA.

HYLODES PHYLLODES. BRAZIL: RIO DE JANEIRO: Angra dos Reis Municipality: Ilha Grande (23°11'S, 44°12'W). Over a small shallow stream on rock, 240 m high in the forest area of Vila Dois Rios, a village in the Atlantic rainforest of the Ilha Grande State Park, an island located in the south of the state of Rio de Janeiro, southeastern Brazil, on 6 January 1997. Male 34.7 mm SVL, collected when calling at 1030 h by C. F. D. Rocha. Museu Nacional do Rio de Janeiro (MNRJ 18809). Verified by José P. Pombal Jr. and Ulisses Caramaschi. First documented record for the state of Rio de Janeiro. At Ilha Grande, this species lives in forests in small shallow streams with many granite boulders. We have found it in different habitats on the island (from sea level up to 300 m elev.), including undisturbed forest, secondary forest with recovering vegetation in the last 20 years, secondary forest with recovering vegetation in the last 50 years, and along trails linking local small villages. In all these habitats *H. phyllodes* is relatively abundant.

Submitted by **CARLOS FREDERICO DUARTE ROCHA** (CNPq grant Nº 300 819/94-3), **MONIQUE VAN SLUYS** (Nº 301 117/95-0) and **FÁBIO H. HATANO** (PIBIC/SR-2/UERJ), Sector de Ecologia, Instituto de Biologia, Universidade do Rio de Janeiro, Rua São Francisco Xavier, 524, Maracanã, Rio de Janeiro, 20550-019, Rio de Janeiro, Brazil.

PLEURODEMA BORELLI (Rufous Four-eyed Frog) ARGENTINA: FORMOSA: Departamento Patiño: Estancia Yacaré, Arroyo Monte Lindo (60°54'W, 24°01'S). 22 November 1944. S. A. Pierotti. Colección Herpetológica Fundación Miguel Lillo, Tucumán, Argentina (FML 00399). Verified by M. L. Lions. First province record; extends range of the species 427 km NE from former records (Cei 1980, Mon. Zool. Ital. (N.S.) Monog. 2:1–597).

Submitted by **JORGE ABEL CESPEDEZ**, Cátedra de Anatomía Comparada, Departamento de Biología, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, CP 3400, Corrientes, Argentina.

PSEUDACRIS CLARKII (Spotted Chorus Frog). USA: TEXAS: Lamb Co: jct. FM 1055 and County Road 184. 2 July 1997. Warren C. Conway, James T. Anderson, and Kenneth G. Ostrand. Museum of Texas Tech University (MTTU 11764). Verified by Ann M. Anderson. County record; many individuals heard calling just after dusk. Expands range of species (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, Texas. 434 pp.).

Submitted by **WARREN C. CONWAY, JAMES T. ANDERSON, KENNETH G. OSTRAND**, Department of Range, Wildlife, and Fisheries Management, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79409, USA.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: ILLINOIS: Scott Co: 1.6 km S jct. U.S. Rt. 67 and I-72 adjacent to Illinois Rt. 100, Sec. 27, T14N, R13W. 27 March 1997. J. K. Tucker, C. A. Phillips, and J. E. Petzing. Illinois Natural History Survey (INHS 12939). Verified by M. Dreslik. New county record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA, **CHRISTOPHER A. PHILLIPS** and **JOHN E. PETZING**, Illinois Natural History Survey, Center for Biodiversity, 607 E. Peabody Drive, Champaign, Illinois 61820, USA.

PSEUDACRIS STRECKERI ILLINOENSIS (Illinois Chorus Frog). USA: ILLINOIS: Scott Co: 1.6 km S jct. U.S. Rt. 67 and I-72 adjacent to Illinois Rt. 100, Sec. 27, T14N, R13W. 27 March 1997. J. K. Tucker, C. A. Phillips, and J. E. Petzing. Illinois Natural History Survey (INHS 12950). Verified by M. Dreslik. First vouchered record for county; other chorus sites were previously reported from the county (Brown and Rose 1988, Illinois Nat. Hist. Surv. Biol. Notes 132:1–13).

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA, **CHRISTOPHER A. PHILLIPS** and **JOHN E. PETZING**, Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

PSEUDACRIS TRISERIATA TRISERIATA (Western Chorus Frog). USA: ILLINOIS: Greene Co: DOR on Hillview-Eldred Road, 1.6 km N Apple Creek, Sec. 21, T11N, R13W. 18 April 1997. J. K. Tucker. Illinois Natural History Survey (INHS 13048). Calhoun Co: 6.4 km S Calhoun/Pike county line adjacent to Illinois Rt. 100 in roadside chorus, Sec. 22, T8S, R2W. 31 May 1997. J. K. Tucker and D. A. Warner. INHS 13043–44. Pike Co: N side of Illinois Rt. 106 at Little Blue Creek, Sec. 30, T5S, R2W. 31 May 1997. J. K. Tucker and D. A. Warner. INHS 13051. All verified by C. A. Phillips. New county records.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA.

PSEUDACRIS TRISERIATA TRISERIATA (Western Chorus Frog). USA: ILLINOIS: Scott Co: E side of Illinois Rt. 100, 1.6 km S jct. U.S. Rt. 67 and I-72, Sec. 27, T14N, R13W. 27 March 1997. J. K. Tucker, C. A. Phillips, and J. E. Petzing. Illinois Natural History Survey (INHS 12940). Verified by M. Dreslik. New county record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA, **CHRISTOPHER A. PHILLIPS** and **JOHN E. PETZING**, Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

RANA CAPITO CAPITO (Carolina Gopher Frog). USA: NORTH CAROLINA: Cumberland Co: 12.6 km NW Cumberland, Fort Bragg Military Reservation. 3 March 1997. Jeffrey C. Beane and Erich L. Hoffman. NCSM 52616–52617. Verified by Alvin L. Braswell. Specimens reared from one of several egg masses found in two adjacent borrow pits. Collected under permit NC-97-ES-45. New county record; extends range ca. 4 km E of nearest records in Hoke County (Beane and Hoffman 1995, Herpetol. Rev. 26:153; NCSM files).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, P.O. Box 29555, Raleigh, North Carolina 27626-0555, USA, and **ERICH L. HOFFMAN**, Fort Bragg DPWE, AFZA-PW-DS Endangered Species Branch, 18th Airborne Corps, Fort Bragg, North Carolina 28307-5000, USA.

SPEA MULTIPLICATA (New Mexico Spadefoot). USA: TEXAS: Cochran Co: 3.94 km W of FM 1780 on County Road 210. 29 June 1997. James T. Anderson, Warren C. Conway, Kenneth G. Ostrand. Museum of Texas Tech University (MTTU 11762). Verified by Ann M. Anderson. Specimen found in roadside pool. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JAMES T. ANDERSON, WARREN C. CONWAY**, and **KENNETH G. OSTRAND**, Department of Range, Wildlife, and Fisheries Management, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79409, USA.

TESTUDINES

EMYDOIDEA BLANDINGII (Blanding's Turtle). USA: NEW YORK: Jefferson Co: crossing Figert Road at jct. with St. Rt. 3 on the Fort Drum Military Reservation (44°03'32"N, 75°33'05"W). 24 July 1995. Morgan McCosh and William Stewart. Adult male, 27 0 mm carapace length, 203 mm plastron length, 1,542 g body mass. Lewis Co: wetland pool on the SE side of RR tracks crossing through Bonaparte Fen between Armitage Road and North Bonaparte Road (44°08'03"N, 75°21'33"W). 27 May 1997. Donald J. Leopold and Dudley J. Raynal. Adult female. Both verified by Alvin R. Breisch. NYSM Color Slide 0001 (Jefferson County specimen) and Color Slide 0002 (Lewis County specimen). Jefferson County specimen is a new county record; extends range ca. 30 km E of known populations (Petokas and Alexander 1978, Herpetol. Rev. 9:107). Lewis County specimen is first county record; extends range another 15 km NE (Petokas and Alexander 1981, New York Fish Game J. 28(1):119–120).

Submitted by **GLENN JOHNSON**, Department of Environmental and Forest Biology, College of Environmental Science and Forestry, State University of New York, Syracuse, New York 13210, USA, and **TODD C. WILLS**, Public Works Environmental Division, Fort Drum, New York 13601, USA.

GRAPTEMYS PULCHRA (Alabama Map Turtle). USA: MISSISSIPPI: Oktibbeha Co: near the confluence of Hollis Creek and Noxubee River, NE 1/4 Sec. 27, T17N, R14E. 10 July 1997. J. Bradford. Mississippi Museum of Natural Science (MMNS 5362). Verified by R. L. Jones. Adult female (PL = 220 mm) accidentally drowned in hoop trap. First county record (Ernst et al. 1994, Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 578 pp.; Jones et al. 1996, Geographic Distribution. *Graptemys pulchra*. Herpetol. Rev. 27:151).

Submitted by **R. BRENT THOMAS**, Department of Biological Sciences, Mississippi State University, Mississippi State, Mississippi 39762, USA, and **JOHNNY BRADFORD**, U.S. Fish and Wildlife Service, Noxubee Refuge, Brooksville, Mississippi, USA.

SIEBENROCKIELLA CRASSICOLLIS (Black Marsh Turtle). INDONESIA: BULITUNG ISLAND: an unnamed small stream, ca. 3 mi S Tanjung Padang (2°45'S, 107°37'E). 6 March 1996. Naoki Kamezaki. Herpetological Collection, Depertment of Zoology, Kyoto University (KUZ 19999). Verified by H. Ota. First record from island (Iverson 1992, A Revised Checklist with Distributional Maps of the Turtles of the World, Privately Printed, Richmond, Indiana. 363 pp.). Adult male (164.8 mm CL, 131.8 mm PL, 525 g body mass). At the collecting site, the stream was ca. 4 m wide with a muddy bottom. The species occurred sympatrically with *Cuora amboinensis*.

Submitted by **YUICHIROU YASUKAWA**, Tropical Biosphere Research Center, University of the Ryukyus, Nishihara, Okinawa 903-01, Japan, and **NAOKI KAMEZAKI**, Graduate School of Human and Environmental Studies, Kyoto University, Sakyo, Kyoto 606-01, Japan.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: ILLINOIS: Calhoun Co: DOR on Illinois River Road, near Pohlman Slough, Sec. 2, T13S, R1W. 6 June 1996. J. K. Tucker. Illinois Natural History Survey (INHS 13057). Verified by C. A. Phillips. New county record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA, and **DANIEL A. WARNER**, Iowa State University, Department of Animal Ecology, Ames, Iowa 50011, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: WISCONSIN: La Crosse Co: Mississippi River, Sec. 14, T16N R8W, UTM coordinates 4857532N, 636936E. 24 July 1997. Andrew Bartels and Eric Kramer. MPM 30227. Verified by Robert W. Henderson. Specimen drowned in submerged fyke net set for fish sampling in backwater in ca. 1 m of water over a soft silt/sand substrate. Collectors noted that this was the first observation of this species in nine years of continuous fish sampling at this site. New county record, within large gap in expected range between Trempealeau and Grant counties (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus. Milwaukee, Wisconsin. 87 pp.)

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA.

TESTUDO MARGINATA (Marginated Tortoise). GREECE: PELOPONNISOS: Island of Sapientza and Island of Sfaktiria, two small rocky islands, the smaller distance of which from the SW end of Peloponnisos being ca. 1500 m southwards and 150 m westwards, respectively. 5 September 1996 and 8 September 1996, respectively. G. Chiras and B. P. Chondropoulos. Zoological Museum of University of Patra (ZMUP A-R 1376 and ZMUP A-R 1377, respectively) (color photograph records). Verified by E. Valakos. The Sapientza population lives in a habitat with tall, rather sparse maquis vegetation mainly consisting of *Arbutus* sp., *Phillyrea media*, *Quercus coccifera*, and *Pistacia lentiscus*, whereas on Sfaktiria these tortoises were encountered in areas with more dense and lower maquis dominated by the latter two of the above species. Both populations seem to be small, but demographically healthy; about a dozen young and older individuals were observed on each island during the one day trip.

No collection was made since *Testudo marginata* is a species protected by international conventions (Bern, CITES), the European Community Directive 92/43, and Greek law; it is also included in official international catalogues of threatened animal taxa. Furthermore, both Sapientza and Sfaktiria islands are parts of two sites proposed for accession to the European network of protected areas (Natura 2000). Both the registered populations are obviously isolated and marginal since the natural range of the species extends into the southern Balkans only (the population in Sardinia, Italy, is almost certainly introduced) (Arnold et al. 1978, Reptiles and Amphibians of Britain and Europe. Collins, London. 272 pp.; Haxhiu 1985, Rezultate to Studimit te Breschkave to Vendit Tone. Buletin I Shkencave te Natyres 2:99–104, translated by J. Buskirk, 1995 Chel. Conserv. Biol. 1:324–327.

Submitted by **BASIL P. CHONDROPOULOS**, Section of Animal Biology, Department of Biology, University of Patra, 260 01 Patra, Greece, and **GEORGE CHIRAS**, Sarantaporou 38, 262 23 Patra, Greece.

SAURIA

ANOLIS RECONDITUS (Blue Mountains Anole). JAMAICA: St. Andrew Parish: ca 0.6 km S Newcastle entrance, 0.48 road km N of milestone 17 from Kingston, ca 900 m., 1650 h (twilight). 26 February 1993. Numi C. Mitchell. MCZ A11595 (male) and A11596 (female). Verified by James Lazell. Extends known range ca. 1 km SE 19-mile Gully where they were observed by Hicks (1973. Breviora 404:1–23) and 2.4 km SW Hardwar Gap, the southernmost locality from which there are voucher specimens (Lazell 1966. Bull. Inst. Jamaica Sci. Series 18[1]:1–15).

Submitted by **NUMI C. MITCHELL**, The Conservation Agency Branch Office, 67 Howland Avenue, Jamestown, Rhode Island 02835, USA.

CNEMIDOPHORUS SEXLINEATUS VIRIDIS (Prairie Racerunner). USA: TEXAS: HOWARD CO: 9.66 road km W Big Spring on Texas Rt. 176 and ca. 0.805 road km N of Texas Rt. 176 on dirt road (32°16'31.6"N, 101°35'55.6"W). 27 July 1997. Toby J. Hibbitts. TCWC 76996. Verified by James R. Dixon. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.; Dixon 1996, Texas Herpetol. Soc. Spec. Publ. No. 2).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

DIPLOGLOSSUS MONOTROPIS. COSTA RICA: HEREDIA: La Selva Biological Station, confluence of Rio Sarapiqui and Rio Puerto Viejo, 10°26'N, 83°59'W, elev. 40 m. 23 March 1997. Ronald M. Coleman. MVZ Color Slide 226066. Verified by Harry Greene. Single individual found at 1730 h (dusk) on concrete path/stairway leading from the Rio Puerto Viejo to the River Station building. Ca. 5 m from water's edge, 5 m above water line, disturbed riparian habitat, but within 25 m of secondary rainforest. First record for La Selva Biological Station; closest previous records in Costa Rica are from Cariblanco, 25 km SW (UCR 672) and the Rio Frio, 90 km NW (UCR 7606, LACM 44999). An uncataloged sighting exists for Chilamate, 7 km E of La Selva (Craig Guyer, pers. comm.).

Submitted by **RONALD M. COLEMAN**, Department of Integrative Biology, University of California, Berkeley, California 94720-3140, USA.

GYMNOPHTHALMUS UNDERWOODI. LESSER ANTILLES: Barbuda: just S Codrington. 21 July 1994. John Mussington. CM 146423. Verified by Ronald I. Crombie. Northernmost record for species. Previously recorded from Guadeloupe (Vanzolini 1990, Herpetol. Rev. 21:96; Schwartz and Thomas 1975, Carnegie Mus. Nat. Hist. Spec. Pub. 1:1–216), Dominica (Brooks 1983, Herpetol. Rev. 14:31), Grenadines (Lazell and Sinclair 1990, Herpetol. Rev. 21:96), St. Vincent, Barbados, Trinidad and Tobago (Schwartz and Thomas 1975, *op. cit.*).

Submitted by **ELLEN J. CENSKY**, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, Pittsburgh, Pennsylvania 15213, USA, and **KEVIN LINDSAY**, Island Resources Foundation, P.O. Box 103, St. John's, Antigua, West Indies.

SERPENTES

BOTHROPS FONSECAI (Fonseca's Lancehead). BRAZIL: SÃO PAULO: Espírito Santo do Pinhal (ca. 22°10'S; 46°46'W) in coffee farm, ca. 880 m elev. 19 July 1996. Collected by plantation workers. Unversidade Estadual de Campinas (ZUEC 01982, 1985). Verified by Ivan Sazima. These specimens extend the range in the state of São Paulo ca. 140 km northwestward (Campbell and Lamar 1989, Venomous Reptiles of Latin America. Comstock, Ithaca, New York. 425 pp.).

Submitted by **PAULO ROBERTO MANZANI**, Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, 13083-970 Campinas, São Paulo, Brazil, **RONILSON AGNALDO MORENO**, Departamento de Farmacologia, Faculdade de Ciências Médicas, Universidade Estadual de Campinas, 13083-970 Campinas, São Paulo, Brazil, and **MIGUEL NASSIF MATTAR**, Fundação Pinhalense de Ensino, Avenida Hélio Vergueiro Leite 1, 13990-000 Espírito Santo do Pinhal, São Paulo, Brazil.

COLUBER CONSTRICTOR FOXII (Racer). USA: ILLINOIS: SCOTT CO: DOR on Hillview-Eldred Road, 4 km SSW Glascow, Sec. 35, T13N, R13W. 5 April 1997. J. K. Tucker. Illinois Natural History Survey (INHS 12962). Verified by C. A. Phillips. New county record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA.

LAMPROPELTIS TRIANGULUM SYSPILA (Red Milk Snake). USA: ILLINOIS: MADISON CO: DOR on Ill. Rt. 100, 2.4 km S Clifton Terrace Road, Sec 4, T6N, R10W. 8 May 1997. J. K. Tucker and M. M. Tucker. Illinois Natural History Survey (INHS 13060). Verified by C. A. Phillips. New county record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Great Rivers Field Station, 4134 Alby Street, Alton, Illinois 62002, USA, and **MOYNELL M. TUCKER**, 120 W. Main, Grafton, Illinois 62037, USA.

MASTICOPHIS MENTOVARIUS MENTOVARIUS (Neotropical Whipsnake). MEXICO: TABASCO: 18 km E Frontera. 7 September 1976. Diderot F. Gicca. UF 42337. Verified by F. Wayne King. First record for the state, bridging a coastal gap of over 500 km between records for southern Veracruz and central Campeche (Johnson 1982, Cat. Am. Amph. Rept. 295:1–4).

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, **DAVID CHISZAR**, **HOBART M. SMITH**, and **FRANK VAN BREUKELEN**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

MICRURUS AVERYI (Coral Snake). BRAZIL: MATO GROSSO: Claudia, Fazenda Iracema (11°36'S; 55°09'W). 7 April 1997. Museu de Zoologia da Universidade de São Paulo (MZUSP 11252). Verified by Paulo E. Vanzolini. Adult female (SVL 591 mm, tail 62 mm, ventrals 209, subcaudals 29). First record for the state of Mato Grosso and also the eastermost record for the species. The specimen, which exhibited beak marks, was dropped by a hawk shot on the wing.

Submitted by **MYRIAM E. VELLOSO CALLEFFO**, Laboratório de Herpetologia, Instituto Butantan, Avenida Vital Brasil, 1500, CEP 05503-900, São Paulo, São Paulo, Brazil.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). LESSER ANTILLES: ANGUILLA: Mead's Bay, Mallihouana Hotel. 28 March 1996 and 25 August 1996. Roy Thomas and Anna Kennedy. Carnegie Museum of Natural History (CM 145826–827). Verified by Addison Wynn. First record for the West Indies. Other records for the New World include introductions to the United States (reviewed in Crawford and Somma 1993, Herpetol. Rev. 24:68; Meshaka 1994, Herpetol. Rev. 25:34; Thomas 1994, Herpetol. Rev. 25:34), Mexico (reviewed in Mendoza Quijano et al. 1994, Herpetol. Rev. 25:34; Eliosa Leon et al. 1995, Herpetol. Rev. 26:110), and Guatemala (Dixon and Hendricks 1979, Zool. Verhandelingen 173:1–39). Specimens were unearthed while digging holes for tree planting on hotel grounds. Presumably introduced on imported plant materials.

Submitted by **ELLEN J. CENSKY**, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, Pittsburgh, Pennsylvania 15213, USA, and **KARIM HODGE**, Anguilla National Trust, The Valley, Anguilla, British West Indies.

STORERIA OCCIPITOMACULATA OBSCURA (Florida Redbelly Snake). USA: TEXAS: San Augustine Co: W side of jct. U.S. Rt. 96 on Texas Rt. 103 (31°24'20.6"N, 94°03'35.8"W). 12 August 1997. Toby J. Hibbitts and John H. Malone. TCWC 76995. Verified by James R. Dixon. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.; Dixon 1996, Texas Herpetol. Soc. Spec. Publ. No. 2).

Submitted by **TOBY J. HIBBITTS**, and **JOHN H. MALONE**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

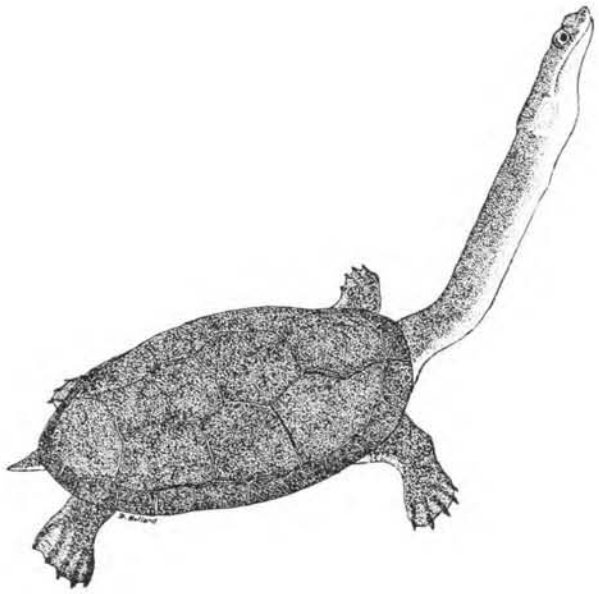
TANTILLA RUBRA (Red Blackhead Snake). GUATEMALA: HUEHUETENANGO: 12 km SSE La Democracía, 950 m (91°50'58"W, 15°31'22"N, GIS portable recorder). 11 March 1991. Steven P. Christman. UF 96323. Verified by Jonathan A. Campbell. First record for Guatemala (Campbell 1989, Proc. West. Found. Vert. Zool. 4(1):1–21) and a range extension of ca. 50 km.

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, and **HOBART M. SMITH, FRANK VAN BREUKELEN** and **DAVID CHISZAR**, University of Colorado Museum, Boulder 80309-0218, USA.

THAMNOPHIS MARCIANUS MARCIANUS (Checkered Garter Snake). USA: CALIFORNIA: Riverside Co: Mecca, 62nd Avenue and Johnson Street. 19 April 1997. Bradford D. Hollingsworth and Todd R. Prosser. La Sierra University Photographic Collection (LSUPC) 941. Verified by L. Lee Grismer. Specimen was found DOR between an open grape field and an orange grove. The nearest distributional records occur in the agricultural regions of the Imperial Valley, south of the Salton Sea (Rossman et al. 1996, The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman, Oklahoma. 325 pp.). The areas surrounding Mecca in the Coachella Valley, north of the Salton Sea, are primarily agricultural lands and separated from those in the Imperial Valley by 20 miles of native desert along the eastern shore of the Salton Sea. The two regions are connected by the Coachella Canal. It appears *T. maricanus* is expanding its range to the north in association with the growing agricultural industry in this area (Glaser 1970. The Distribution of Amphibians and Reptiles in Riverside County, California, Riverside Museum Press, Riverside, California, p. 38). The only other Riverside County records are along the Colorado River and its adjacent irrigated areas (Glaser 1970, *op. cit.*).

Submitted by **BRADFORD D. HOLLINGSWORTH**, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA, and **TODD R. PROSSER**, 1591 Stoddard Avenue, Thousand Oaks, California 91360, USA.

TRIMORPHODON TAU TAU (Mexican Lyre Snake, Falsa Nauyaca Mexicano). MÉXICO: TAMAULIPAS: 40 km NE San Fernando on México Rt. 101. 20 December 1952. Rezneat M. Darnell and Ernest A. Liner. DOR. TU 15441. Verified by Hobart M. Smith. Female with scale counts within the subspecies range; extends range 150 km NNE of Santander Jiménez, Tamaulipas (Brown and Brown 1967, Texas J. Sci. 19:323–326) and 199 km ENE of Iturbide region, Nuevo León (Blody et al. 1987, Herpetol. Rev. 18:21; Lazcano et al. 1992, Bull. Chicago Herpetol. Soc. 27:4). Contrary to the town name Jiménez, as stated by Brown and Brown (*op. cit.*) and by McDiarmid and Scott (1970, Los Angeles Co. Mus. Cont. Sci. 179:1–43), the correct name of the town is Santander Jiménez. Also, the Brown and Brown reference (*op. cit.*) is in volume 19, not 29, as stated in McDiarmid and Scott (*op. cit.*).



Submitted by **HAROLD A. DUNDEE**, Tulane University Museum of Natural History, Belle Chasse, Louisiana 70037-3098, USA, and **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

UNGALIOPHIS CONTINENTALIS (Isthmian Dwarf Boa). NICARAGUA: MATAGALPA: Selva Negra, 1300 m elev. (12°59'96"N, 85°54'55"W). March 1995. G. Köhler. Forschungsinstitut und Naturmuseum Senckenberg (SMF 77558). Verified by W. Böhme. First record for Nicaragua; extends range ca. 160 airline km SE of record from La Montanita, Departamento Francisco Morazán, Honduras (Wilson and Meyer 1985, The Snakes of Honduras. Second Ed. Milwaukee Publ. Mus., Wisconsin. 150 pp.; Villa and Wilson 1990, Cat. Amer. Amphib. Rept. 480:1–4).

Submitted by **GUNTHER KÖHLER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a.m., Germany.

UROMACERINA RICARDINII (Cobra-cipó, São Paulo Sharp Snake). BRAZIL: ESPÍRITO SANTO: Municipality of Marechal Floriano: Alto Nova Almeida near Sítio Tres Marias (20°24'36"S; 40°49'26"W, ca. 680 m). 16 January 1996. Josimar Luís da Silva. Coleção Zoológica da Universidade Federal do Espírito Santo (ZUFES 150390). Verified by Ivan Sazima and Paulo Roberto Manzani. First record for state; extends known distribution northwards in the Atlantic Forest domain. Previously known from the state of Rio de Janeiro, south to the state of Rio Grande do Sul (Hoge 1957/58, Mem. Inst. Butantan 28:77–82; Peters and Orejas Miranda 1970, Bull. U.S. Nat. Mus. 297:321; Müller 1978, Salamandra 14:44; Lema 1973, Iheringia 44:64–73). An apparently disjunct population was discovered in the Amazonian forest in the state of Pará (Cunha and Nascimento 1982, Bol. Mus. Para. Emílio Goeldi 113:1–9).

Submitted by **CLAUDIO ZAMPROGNO**, Departamento de Biologia, Universidade Federal do Espírito Santo, 29040-090 Vitória, Espírito Santo, Brazil. E-mail: czamprog@server.npd.ufes.br.

Early Rewards from the Georgia Herp Atlas

JOHN B. JENSEN
Georgia Department of Natural Resources
Nongame-Endangered Wildlife Program
116 Rum Creek Drive, Forsyth, Georgia 31029, USA

and

ROBERT A. MOULIS
Savannah-Ogeechee Canal Museum
681 Ft. Argyle Road, Savannah, Georgia 31419, USA

Organized by the Georgia Department of Natural Resources, the Georgia Herp Atlas is a volunteer-supported effort to document the current distribution of reptiles and amphibians in the state. Volunteers are asked to provide verifiable evidence of herp observations made in Georgia and include standard collection information: precise locality, date, etc. Because of the strict collecting laws for reptiles and amphibians of Georgia and the large number of volunteers, many observations are substantiated by photographs rather than specimens. Included in this report are county records (Williamson and Moulis 1994) obtained during the inaugural year of the project. All specimens and photographs were deposited in the herpetological collections of either the University of Georgia Museum of Natural History (UGAMNH) or Savannah-Ogeechee Canal Museum (SOCM), as indicated. UGAMNH specimens and photographs were verified by Joshua Laerm, while those deposited in SOCM were verified by Robert Moulis.

CAUDATA

Ambystoma maculatum (Spotted Salamander). USA: GEORGIA: DOUGLAS CO: Sweetwater Creek State Park. June 1996. Dan Emsweller. SOCM 0025.

Plethodon ocmulgee (Ocmulgee Slimy Salamander). USA: GEORGIA: HOUSTON CO: near jct. of Grovania Road and Elko Road (32°22' 08"N, 83°43' 04"W). 9 October 1996. Dan and Pam Guynn. SOCM 0027. JONES CO: jct. of Route 18 and McKay Road (32°58'34"N, 83°36'40"W). 16 April 1994. Lisa Walcott-Moreley and Barbara Edwards. SOCM 0028.

Pseudotriton ruber ruber (Northern Red Salamander). USA: GEORGIA: DOUGLAS CO: Sweetwater Creek State Park. 11 October 1996. Dan and Michelle Emsweller. SOCM 0024.

ANURA

Acris crepitans crepitans (Northern Cricket Frog). USA: GEORGIA: DOOLY CO: Flint River Wildlife Management Area (32°08'13"N, 84°00'43"W). 18 September 1996. John Jensen and Todd Schneider. UGAMNH 27363.

Acris gryllus gryllus (Southern Cricket Frog). USA: GEORGIA: BROOKS CO: Pope's Mill Pond (33°53'54"N, 83°44'27"W). 8 June 1996. John Jensen and Mike Harris. UGAMNH 27362.

Bufo terrestris (Southern Toad). USA: GEORGIA: BIBB CO: Ocmulgee National Monument. 14 April 1996. Lisa Walcott-Moreley, Dan Guynn, and Jerry Amerson. SOCM 0026.

Gastrophryne carolinensis (Eastern Narrowmouth Toad). USA: GEORGIA: BIBB CO: private residence on Gwinnett Drive 0.5 km W of Pierce Avenue, in Macon (32°51'52"N, 83°39'57"W). 26 August 1996. Todd Schneider. UGAMNH 27368.

Hyla avivoca (Bird-voiced Treefrog). USA: GEORGIA: TAYLOR CO: Rombulette Creek at Georgia Hwy 137 (32°28'16"N, 84°21'32"W). 15 July 1996. John and Jodie Jensen. UGAMNH 27361.

Hyla cinerea (Green Treefrog). USA: GEORGIA: BIBB CO: Ocmulgee National Monument. 15 October 1995. Lisa Walcott-Moreley. SOCM 0029. DOOLY CO: Flint River Wildlife Management Area (32°08'13"N, 84°00'43"W). 18 September 1996. John Jensen and Todd Schneider. SOCM 0030. MORGAN CO: Monticello Road 6.5 km S of Madison (33°31'02"N, 83°31'59"W). 25 September 1996. George West. SOCM 0031.

Hyla squirella (Squirrel Treefrog). USA: GEORGIA: TAYLOR CO: AOR. U.S. Hwy 19 0.2 km N of Ga. Hwy. 90 (32°26'34"N, 84°16'38"W). 15 July 1996. John and Jodie Jensen. UGAMNH 27360.

Pseudacris crucifer crucifer (Northern Spring Peeper). USA: GEORGIA: NEWTON CO: near confluence of Cornish Creek and Alcovy River (33°36'56"N, 83°48'11"W). 16 June 1996. John Jensen and Betsie Rothermel. UGAMNH 27340. TAYLOR CO: Cedar Creek at U.S. Hwy 19 (32°23'22"N, 84°17'48"W). John and Jodie Jensen. UGAMNH 27364.

Rana clamitans clamitans (Bronze Frog). USA: GEORGIA: NEWTON CO: near confluence of Cornish Creek and Alcovy River (33°36'56"N, 83°48'11"W). 6 July 1996. John Jensen and Betsie Rothermel. SOCM 0032.

Rana grylio (Pig Frog). USA: GEORGIA: BROOKS CO: Pope's Mill Pond (33°53'54"N, 83°44'27"W). 8 June 1996. John Jensen and Mike Harris. UGAMNH 27366, 27367.

Rana palustris (Pickerel Frog). USA: GEORGIA: WALKER CO: just north of Atwood Point Road approximately 0.3 km E of jct. with McCutchens Springs Road, on Pigeon Mountain (34°41'13"N, 85°23'00"W). 13 August 1996. John Jensen. UGAMNH 27365.

TESTUDINES

Chelydra serpentina serpentina (Common Snapping Turtle). USA: GEORGIA: COBB CO: Cameron Station Apartments at Franklin Road (33°55'58"N, 84°30'01"W). 18 September 1996. Tim Matthews. SOCM 0042. FAYETTE CO: Morning Creek near confluence with Flint River (33°27'59"N, 84°23'22"W). 25 August 1996. Sean Graham. SOCM 0043.

Pseudemys concinna concinna (Eastern River Cooter). USA: GEORGIA: MONROE CO: Lake Juliette (33°02'N, 83°48'W). 4 June 1996. Ben Granitz. SOCM 0034.

Sternotherus minor minor (Loggerhead Musk Turtle). USA: GEORGIA: CLAYTON CO: Flint River near Jonesboro. 28 August 1996. Sean Graham. SOCM 0033.

Sternotherus odoratus (Common Musk Turtle). USA: GEORGIA: MONROE CO: AOR US Hwy. 23 2.0 mi N of Ga. Hwy 18. Jerry Payne. UGAMNH 27342.

Terrapene carolina (Box Turtle). USA: GEORGIA: DOUGLAS CO: Sweetwater Creek State Park. 8 September 1996. Dan Emsweller. SOCM 0037. HOUSTON CO: near jct. of Grovania Road and Elko Road (32°22'29"N, 83°43'04"W). 12 August 1996. Dan Guynn. SOCM 0038. MONROE CO: D.O.R. Route 42 3.9 km N of jct with Route 74. 15 September 1996. Giff Beaton. SOCM 0039. ROCKDALE CO: A.O.R. Old Covington Road just east of Salem Road. 7 August 1996. Marci DeSart and Mike Armstrong. SOCM 0040. WALTON CO: D.O.R. Troy Smith Road 0.8 km N of jct with U.S. Hwy 78. 13 September 1996. Jeff Parrish. SOCM 0041.

Trachemys scripta scripta (Yellowbelly Slider). USA: GEORGIA: BURKE CO: Di-Lane Plantation: 0.5 km W of Commanche Frank Road, 2.4 km NW of Herndon Road. 14 June 1996. John Jensen, Vic VanSant, and Lynn Lewis. UGAMNH 27341. DOUGLAS CO: Sweetwater Creek State Park. 15 June 1996. Dan and Michelle Emsweller. SOCM 0035. NEWTON CO: near confluence of Cornish Creek and Alcovy River (33°36'56"N, 83°48'11"W). 6 July 1996. Betsie Rothermel. SOCM 0036.

SAURIA

Anolis carolinensis (Green Anole). USA: GEORGIA: CLAYTON CO: S. Hampton Ct., Jonesboro. 20 November 1996. Sean Graham and Josh Eldridge. SOCM 0044. FAYETTE CO: near confluence of Morning Creek and Flint River. 4 December 1996. Sean Graham. SOCM 0045. GILMER CO: White Path Road 3.2 km N of Ga. Hwy. 515. 14 October 1996. Ronny Holcomb. SOCM 0046. GORDON CO: Slatemine Road, west of Fairmount. 31 October 1996. Keith Bailey. SOCM 0047. HENRY CO: Turner Church Road in McDonough. 12 October 1996. Nicole Marlin. SOCM 0048. WALTON CO: River Bluff Road in Monroe. 23 September 1996. Jeff Parrish. SOCM 0049.

Cnemidophorus sexlineatus sexlineatus (Six-lined Racerunner). USA: GEORGIA: JOHNSON CO: near the jct. of Page Road and Bartow-Dublin Road (32°46'58"N, 82 40'08"W). 23 September 1996. James Harrison. SOCM 0050.

Eumeces laticeps (Broadhead Skink). USA: GEORGIA: LAMAR CO: Sappington Road in Redbone community, near Barnseville (32°59'29"N, 84°05'40"W). 30 June 1996. Jim Ozier. UGAMNH 27353.

Ophisaurus ventralis (Eastern Glass Lizard). USA: GEORGIA: BIBB CO: D.O.R. U.S. Hwy 23 1.6 km S of Monroe County line (32°56'29"N, 83°43'10"W). 29 May 1996. John Jensen. UGAMNH 27352.

Sceloporus undulatus hyacinthinus (Northern Fence Lizard) USA: GEORGIA: DOUGLAS CO: Sweetwater Creek State Park. 11 October 1996. Dan and Michelle Emsweller. SOCM 0051.

Sceloporus undulatus undulatus (Southern Fence Lizard) USA: GEORGIA: JOHNSON CO: near the jct. of Page Road and Bartow-Dublin Road (32°46'58"N, 82°40'08"W). 23 September 1996. James Harrison. SOCM 0052.

SERPENTES

Agkistrodon contortrix mokasen (Copperhead) USA: GEORGIA: GWINNETT CO: jct. of Shelburne Trace and Overlook View Drive, in Duluth. 26 September 1996. Carol Lowe. SOCM 0053.

Crotalus adamanteus (Eastern Diamondback Rattlesnake). USA: GEORGIA: TOOMBS CO: D.O.R. Ga. Hwy 86 3.2 km N of Ga. Hwy 152 (32°18'35"N, 82°15'49"W). 13 October 1996. Anselm Atkins and Margaret Kavanaugh. SOCM 0055.

Crotalus horridus (Timber Rattlesnake). USA: GEORGIA: MONROE CO: near jct. of McCrackin Road and Juliette Road, in Juliette. 16 August 1996. Ed Williams. UGAMNH 27344.

Diadophis punctatus punctatus (Southern Ringneck Snake). USA: GEORGIA: FAYETTE CO: private residence on Summer Place in Peachtree City. 29 September 1996. Brad Koehn, Andrew Harlfinger, and Matt Harlfinger. SOCM 0056.

Elaphe obsoleta obsoleta (Black Rat Snake). USA: GEORGIA: CRAWFORD CO: D.O.R. on County Road 115, 1.1 km W of Ga. Hwy. 42. 15 September 1996. Giff Beaton. SOCM 0057. GILMER CO: A.O.R., Legion Road ca. 3 km S of Ellijay. 4 October 1996. Ronny Holcomb. SOCM 0059. LAMAR CO: Sappington Road in Redbone community, near Barnseville (32°59'29"N, 84°05'40"W). August 1996. Jim Ozier. SOCM 0060. MONROE CO: Ga. Hwy 18 1.1 km W of Rum Creek Drive (33°56'26"N, 83°43'10"W). 17 May 1996. John Jensen. UGAMNH 27351. WALTON CO: private residence on Tara Blvd., in Loganville. September 1996. David Funderburk. SOCM 0061.

Elaphe obsoleta obsoleta x *spiloides* (Intergrade Rat Snake). USA: GEORGIA: DOUGLAS CO: Sweetwater Creek State Park. April 1996. Dan and Michelle Emsweller. SOCM 0058a, 0058b.

Heterodon platirhinos (Eastern Hognose Snake). USA: GEORGIA: CANDLER CO: D.O.R. Ga. Hwy. 121-23 ca. 150 m N of Canoochee River. 13 October 1996. Anselm Atkins and Margaret Kavanaugh. SOCM 0062.

Lampropeltis getula getula (Eastern Kingsnake). USA: GEORGIA: DOUGLAS CO: near jct. of Kings Hwy. and Queens Road. 5 September 1996. Dan Emsweller. SOCM 0063. LAMAR CO: Sappington Road 0.8 km E of Community House Road. 9 August 1996. Jim Ozier. SOCM 0064.

Lampropeltis triangulum elapsoides (Scarlet Kingsnake). USA: GEORGIA: WAYNE CO: adjacent to Ingram Road (31°39'38"N, 82°06'41"W). 18 April 1996. Robert Moulis and Jerry Williamson. SOCM 0008, 0009.

Nerodia erythrogaster erythrogaster (Redbelly Water Snake). USA: GEORGIA: CALHOUN CO: County Road 40 at Spring Creek (31°27'59"N, 84°26'56"W). 4 September 1996. John Jensen. SOCM 0065.

Nerodia floridana (Florida Green Water Snake). USA: GEORGIA: BURKE CO: A.O.R. Old River Road 1 km N of Sweetwater Creek (33°02'54"N, 81°36'29"W). 3 August 1996. Robert Redmond and James Waters. SOCM 0010.

Nerodia sipedon pleuralis (Midland Water Snake). USA: GEORGIA: FAYETTE CO: Flint River 0.4 km N of confluence with Morning Creek. 17 September 1996. Sean Graham. SOCM 0066.

Nerodia taxispilota (Brown Water Snake). USA: GEORGIA: CALHOUN CO: County Road 40 at Spring Creek (31°27'59"N, 84°26'56"W). 4 September 1996. John Jensen. SOCM 0067.

Opheodrys aestivus (Rough Green Snake). USA: GEORGIA: DOUGLAS CO: Sweetwater Creek State Park. 18 September 1996. Dan and Michelle Emsweller. SOCM 0068. GILMER CO: AOR. Ga. Hwy 515 ca. 7 km S of Ellijay. 2 October 1996. Ronny Holcomb. SOCM 0069. PUTNAM CO: Great Waters Golf Course at Reynolds Plantation. 17 September 1996. George West. SOCM 0070. WALTON CO: ca. 0.5 km N of jct. Georgia Hwy. 278 and New Hope Church Road, in between city limits (33°49'18"N, 83°48'20"W). 24 July 1996. Charles Rabolli. SOCM 0071.

Pituophis melanoleucus mugitus (Florida Pine Snake). USA: GEORGIA: WHEELER CO: DOR. U.S. Hwy. 280 0.6 km E of U.S. Hwy. 319 (32°05'22"N, 82°52'01"W). May 1996. Timmy Arbogast. SOCM 0019.

Regina septemvittata (Queen Snake). USA: GEORGIA: DOUGLAS CO: Sweetwater Creek State Park. 14 April 1996. Dan and Michelle Emsweller. SOCM 0072.

Storeria dekayi wrightorum (Midland Brown Snake). USA: GEORGIA: DOOLY CO: Flint River Wildlife Management Area (32°08'13"N, 84°00'43"W). 18 September 1996. John Jensen and Todd Schneider. SOCM 0073.

Storeria dekayi dekayi x *wrightorum* (Brown Snake). USA: GEORGIA: FAYETTE CO: near confluence of Morning Creek and Flint River. 4 March 1996. Sean Graham. SOCM 0074.

Storeria occipitomaculata occipitomaculata (Northern Redbelly Snake). USA: GEORGIA: BIBB CO: near the dam at Lake Tobesofkee. 8 September 1996. Jodie Jensen. UGAMNH 27350. WASHINGTON CO: private residence on Ridgeland Drive, in Sandersville (32°59'17"N, 82°48"54"W). 10 November 1996. Bobby Strange. SOCM 0075.

Thamnophis sauritus sauritus (Eastern Ribbon Snake). USA: GEORGIA: LAMAR CO: DOR. Ramah Church Road 0.8 km E of Community House Road, in Redbone Community (32°58'57"N, 84°04'29"W). August 1996. Jim Ozier. SOCM 0076.

Thamnophis sirtalis sirtalis (Eastern Garter Snake). USA: GEORGIA: DOUGLAS CO: near jct. of Kings Hwy. and Queens Road (33°41'03"N, 84°46'50"W). 2 September 1996. Dan and Michelle Emsweller. SOCM 0077. LAURENS CO: Beaverdam Wildlife Management Area (32°40'16"N, 82°56'29"W). 2 November 1996. Robert Moulis and Jeff Cook. SOCM 0023. MONROE CO: DOR. U.S. Hwy 23 5.6 km N of Georgia Hwy 18 (33°03'59"N, 83°46'54"W). 11 June 1996. John Jensen. UGAMNH 27346.

Virginia valeriae (Smooth Earth Snake). USA: GEORGIA: MONROE CO: adjacent to Rum Creek Drive 0.3 km N of Georgia Hwy 18 (33°01'55"N, 83°48'22"W). 5 June 1996. Ted Woodward. UGAMNH 27345.

Recent Amphibian and Reptile Distribution Records for Wisconsin

GARY S. CASPER

Section of Vertebrate Zoology, Milwaukee Public Museum
800 West Wells Street, Milwaukee, Wisconsin 53233, USA
e-mail: gsc@csd.uwm.edu

The following 46 distribution vouchers of amphibians and reptiles represent new county records for Wisconsin based on Casper (1996). These records were acquired through the Wisconsin Herpetological Atlas Project, a scientific program of the Milwaukee Public Museum (http://www.mpm.edu/collect/vertzo/herp/atlas/welcome.html).

All specimens were verified by Robert W. Henderson, except where otherwise noted. Collection acronyms are: MPM—Milwaukee Public Museum, Milwaukee, Wisconsin (numbers prefaced with "P-" refer to photographs); USNM—National Museum of Natural History, Washington, D.C.

CAUDATA

Ambystoma laterale (Blue-spotted Salamander). ADAMS Co: NE 1/4 of SE 1/4 Sec. 36, T18N, R5E. 24 April 1994. Bill Miller. MPM P-545. New county record; fills distribution gap in central Wisconsin (Casper 1996). Specimen found under plywood sheet at yard edge abutting oak woods.

Ambystoma maculatum (Spotted Salamander). CHIPPEWA Co: 205th Avenue, E 1/2 Sec. 26, T31N, R8W. 29 September 1995. Janine Polk. MPM P-592. New county record; slightly extends range south by ca. 25 km in northwestern Wisconsin (Casper 1996; Vogt 1981), but still north of the tension zone where the northern hardwoods province begins to change into the southern prairie forest province (Curtis 1959).

Ambystoma tigrinum tigrinum (Eastern Tiger Salamander). CHIPPEWA Co: County Line Road "a bit east" of Sherman Creek, S 1/2 Sec. 35, T28N, R10W. 30 September 1995. Janine Polk. MPM P-595. New county record (Casper 1996), very close to Eau Claire County record mapped by Vogt (1981). Collector watched specimen crawl across road from Chippewa County to Eau Claire County. TREMPEALEAU Co: Rt. 10 just E of Buffalo County line, SW 1/4 Sec. 6, T24N, R9W. 11 August 1996. Janine Polk. MPM P-549. New county record (Casper 1996), extends range ca. 25 km south from closest point plotted by Vogt (1981) in northwestern Wisconsin.

Hemidactylium scutatum (Four-toed Salamander). CHIPPEWA Co: just off Moon Ridge Trail (245th Avenue) and Norway Trail, NE 1/4 Sec. 5, T31N, R7W. 14 July 1996. Janine Polk. MPM P-550. New county record (Casper 1996). In rotten log in maple woods near stream and marsh.

Necturus maculosus maculosus (Common Mudpuppy). IRON Co: Secs. 17/18, T43N, R3E. September 1994. J. Zarzycki. MPM P-576. New county record within expected range (Casper 1996). RUSK Co: SW 1/4 of SW 1/4 Sec. 26, T35N, R6W. 22 August 1994. Christian W. Cold. MPM P-568. New county record within expected range (Casper 1996).

Notophthalmus viridescens louisianensis (Central Newt). CHIPPEWA Co: 225th Avenue, W 1/2 Sec. 16, T31N, R8W. 29 September 1995. Janine Polk. MPM P-591. New county record (Casper 1996) in center of large distributional gap mapped by Vogt (1981) and Conant and Collins (1991) in west-central Wisconsin. This distributional gap should now be considered an artifact of collecting bias.

Plethodon cinereus (Redback Salamander). CHIPPEWA Co: near Deer Fly Trail, SE 1/4 Sec. 2, T31N, R8W. 10 August 1996. Janine Polk. MPM P-551. New county record expanding distribution in west-central Wisconsin (Casper 1996). Under log in mature maple woods. This record and recent records for Dunn and Pierce counties (Casper 1996) warrant including all of northwestern Wisconsin within the expected range, thereby updating the distribution mapped by Conant and Collins (1991).

ANURA

Hyla chrysoscelis (Cope's Gray Treefrog). CHIPPEWA Co: SE 1/4 of SW 1/4 Sec. 32, T30N, R7W. 30 May 1995. Janine Polk. Identification by call, MPM audio tape (Cat. No. pending). New county record (Casper 1996); extends range ca. 50 km east in northwestern Wisconsin (Vogt 1981). EAU CLAIRE Co: marsh along Langdell Road, NE 1/4 Sec. 28, T26N, R10W. 31 May 1995. Janine Polk. Identification by call, MPM audio tape (Cat. No. pending). New county record within expected range (Casper 1996). *Hyla versicolor* was calling at same site. PEPIN Co: small marsh along Rt. H, NE 1/4 Sec. 11, T25N, R11W. 31 May 1995. Janine Polk. Identification by call, MPM audio tape (Cat. No. pending). New county record, continuing documentation of distribution in west central Wisconsin (Casper 1996). RUSK Co: along 45 Road, SW 1/4 Sec. 16, T33N, R8W. 1 June 1996. Janine Polk. Identification by call, MPM audio tape (Cat. No. pending). New county record (Casper 1996); extends range ca. 50 km east in northwestern Wisconsin (Vogt 1981).

Hyla versicolor (Gray Treefrog). EAU CLAIRE Co: marsh along Langdell Road, NE 1/4 Sec. 28, T26N, R10W. 31 May 1995. Janine Polk. Identification by call, MPM audio tape (Cat. No. pending). New county record filling distributional gap in west central Wisconsin (Casper 1996). *Hyla chrysoscelis* was calling at same site.

Pseudacris crucifer crucifer (Northern Spring Peeper). PEPIN Co: small marsh along Rt. H, NE 1/4 Sec. 11, T25N, R11W. 31 May 1995. Janine Polk. Identification by call, MPM audio tape (Cat. No. pending); new county record completing distribution in west central Wisconsin (Casper 1996). ROCK Co: wetland on west side of Eagle Road 0.3 mi. north of Gibbs Lake Road, NE 1/4 of SE 1/4 Sec. 22, T4N, R1E. 19 April 1995. Kathy Kirk. Identification by call, MPM audio tape (Cat. No. pending); new county record adding to southern Wisconsin range (Casper 1996). RUSK Co: W7047 Broken Arrow Road, NE 1/4 of NE 1/4 Sec. 19, T33N, R5W. 8 September 1996. Earl Meyer. MPM P-558; near Storm Road, NW 1/4 of NW 1/4 Sec. 19, T34N, R6W. 20 August 1994. Christian W. Cold. MPM P-566. New county record completing distribution in northwestern Wisconsin (Casper 1996). Considered a common frog in Rusk County.

Pseudacris triseriata (Western Chorus Frog). IRON Co: Threeten Road, NW 1/4 of SW 1/4 Sec. 22, T43N, R3E. 26 May 1996. Bruce Bacon. Identification by call, MPM audio tape (Cat. No. pending). New county record (Casper 1996) for northern Wisconsin, where this species is rare and local; calling from shallow sedge meadow. RUSK Co: Potato Creek Wildlife Area, NW 1/4 Sec. 20, T33N, R8W. 3 May 1996. Janine Polk. Identification by call, MPM audio tape (Cat. No. pending). New county record within expected range (Casper 1996).

Rana septentrionalis (Mink Frog). CHIPPEWA Co: on Bob Lake Road (175th Street), S 1/2 Sec. 23, T31N, R8W. 29 September 1995. Janine Polk. MPM P-593. New county record (Casper 1996); extends range ca. 50 km west and 85 km south of localities mapped by Vogt (1981). RUSK Co: near south shore Perch Lake off Perch Lake Road, NE 1/4 of NE 1/4 Sec. 1, T35N, R9W. 13 August 1994. Christian W. Cold. MPM P-565. New county record within expected range (Casper 1996).

Rana sylvatica (Wood Frog). RUSK Co: Potato Creek Wildlife Area at jct Rt. D and 45 Road, SW 1/4 Sec. 16, T33N, R8W. 3 May 1996. Janine Polk. Identification by call, MPM audio tape (cat. no. pending); NE 1/4 of NE 1/4 Sec. 19, T33N, R5W. 8 May 1996. Earl Meyer. Identification by call, MPM audio tape (cat. no. pending). New county record within expected range (Casper 1996).

TESTUDINES

Apalone mutica mutica (Midland Smooth Softshell). IOWA Co: channel of Wisconsin River, 2.5 mi W Gotham, Sec. 35, T9N, R1E. 13 August 1995. Steve Thiessen. MPM P-598. New county record (Casper 1996), contributing to continuous distribution in Wisconsin River.

Apalone spinifera (Spiny Softshell). DOUGLAS Co: Eau Claire River along Rt. Y, W 1/2 of SW 1/4 of SW 1/4 Sec. 24, T44N, R10W. 13 August 1995. Steve Thiessen. MPM P-598. New county record (Casper 1996), supporting unverified localities mapped by Vogt (1981), and confirming northern limit of range in western Wisconsin (Conant and Collins 1991).

Clemmys insculpta (Wood Turtle). BARRON Co. 8 July 1996. Randy McDonough and Steve Ward. MPM P-577. New county record within expected range (Casper 1996). Found in mixed hardwood forest 0.25 mi from nearest creek. Locality to quarter section available on request from Milwaukee Public Museum.

Emydoidea blandingii (Blanding's Turtle). BARRON Co: 4 mi NE Cumberland, 0.25 mi from Yellow River, NW 1/4 of NE 1/4 Sec. 22, T36N, R13W. 19 June 1995. David Evenson. MPM P-590. New county record, expanding northwestern Wisconsin range (Casper 1996). FOND DU LAC Co: Kettle Moraine State Forest, Long Lake campground, N 1/2 Sec. 25, T14N, R19E. July 1995. Jeff Lorch. MPM P-602. New county record expanding range in east central Wisconsin (Casper 1996).

Graptemys geographica (Common Map Turtle). CRAWFORD Co: Prairie du Chien, presumably Mississippi River, T7N, R7W. 30 August 1927. Francis M. Uhler. USNM 288149. Verified by Ronald I. Crombie. New county record (Casper 1996); fills distributional gap along Mississippi River in southwestern Wisconsin. WAUSHARA Co: Lake Alpine in Willow Creek basin of Fox River watershed, Sec. 4, T18N, R11E. 1991 & 1996. Roberta Plummer. MPM P-556 and P-584. New county record (Casper 1996); closes distributional gap in central Wisconsin.

Graptemys pseudogeographica pseudogeographica (False Map Turtle). CRAWFORD Co: Prairie du Chien, presumably Mississippi River, T7N, R7W. 30 August 1927. Francis M. Uhler. USNM 288153. Verified by Ronald I. Crombie. New county record (Casper 1996); fills distributional gap along Mississippi River in southwestern Wisconsin.

Sternotherus odoratus (Common Musk Turtle). COLUMBIA Co: Fox River W of Pardeeville, 0.3 mi E Swan Lake, Sec. 5, T12N, R10E. 11 June 1994. Randy Grimes. MPM P-600. New county record (Casper 1996); closes distributional gap in south central Wisconsin. Collector reports species as "fairly common" at the site. RICHLAND Co: on Lone Rock dike near boat landing along Wisconsin River, SE 1/4 Sec. 3, T8N, R2E. 6 June 1995. Al Cornell and Mike Anding. MPM P- 569. New county record (Casper 1996) within continuous lower Wisconsin River distribution.

SERPENTES

Diadophis punctatus edwardsii (Northern Ringneck Snake). DOUGLAS Co: Big Manitou Falls at Pattison State Park, Sec. 22, T47N, R14W. 16 June 1996. Chris Evavold. MPM P-536. New county record (Casper, 1996). Individual found on shaded park trail; extends range ca. 60 km W of verified localities mapped by Vogt (1981) and complements Vogt's unverified central Douglas County record. TAYLOR Co: 18 mi W Medford on Rt. 64, SW 1/4 Sec. 36, T31N, R3W. 19 June 1996. Jon Roti Roti. MPM P-547. New county record within expected range (Casper 1996).

Elaphe vulpina vulpina (Western Fox Snake). ONEIDA Co: 22nd Avenue north of Beaver Avenue, Sec. 4, T19N, R11E. April 1994. Roberta Plummer. MPM P-585. New county record (Casper 1996), adding to north central Wisconsin distribution. WAUSHARA Co: Rt. 17, Sec. 15, T37N, R9E. 30 July 1995. Ronald Eckstein. MPM P-582. New county record within expected central Wisconsin range (Casper 1996).

Heterodon platirhinos (Eastern Hognose Snake). RICHLAND Co: Lone Rock Wildlife Area, Sec. 3, T8N, R2E. 19 May 1995. Steve Thiessen. MPM P-542. New county record (Casper 1996) within documented southwestern Wisconsin range. Individual found at edge of open sand area and pine woods.

Lampropeltis triangulum triangulum (Eastern Milk Snake). RICHLAND Co: Rt. Q, Sec. 28, T10N, R1W. 5 July 1995. Gary Eldred. MPM 28002. Second specimen found 3 mi SE Sylvan, T11N, R2W. 19 July 1934. Charles E. Burt. USNM 99807. Verified by Ronald I. Crombie. This latter specimen was previously reported by Burt (1935) without giving the specimen number, and has been overlooked by subsequent authors. Re-discovered county record (Casper 1996; Vogt 1981); fills gap in southern Wisconsin range. LAFAYETTE Co: Old Rt. Q, SE 1/4 of SW 1/4 Sec. 27, T4N, R5E. 28 May 1995. Gary Eldred. MPM 28004. New county record (Casper 1996); fills gap in southern Wisconsin range.

Nerodia sipedon sipedon (Northern Water Snake). BARRON Co: NE shore of Rice Lake at 89 Monroe Avenue, NE 1/4 Sec. 16, T35N, R11W. 10 July 1996. Elizabeth L. Brown. MPM P-553. New county record (Casper 1996); adds to northwestern Wisconsin range. WAUPACA Co: Anderson Road just N of Rt. 49, E 1/2 Sec. 21, T24N, R11E. 1 October 1996. Mitch Taylor. MPM 27994. New county record (Casper 1996); expands central Wisconsin range.

Pituophis catenifer sayi (Bullsnake). DUNN Co: Red Cedar Road near Chippewa River, NW 1/4 Sec. 32, T26N, R12W. 30 April 1995. Janine Polk. MPM P-561. New county record closing distributional gap between Pierce and Eau Claire counties (Casper 1996); extends range ca. 85 km northwest from nearest confirmed locality mapped by Vogt (1981). RICHLAND Co: just W of Rt. 130 on Rt 14, W of Lone Rock, Sec. 1, T8N, R2E. 19 May 1995. Steve Thiessen. MPM P-597. New county record (Casper 1996); completes continuous distribution along lower Wisconsin River corridor.

Storeria dekayi (Brown Snake). CHIPPEWA Co: 205th Avenue, E 1/2 Sec. 26, T31N, R8W. 29 September 1995. Janine Polk. MPM P-594. New county record filling distributional gap in west central Wisconsin (Casper 1996; Conant and Collins 1991; Vogt 1981).

Storeria occipitomaculata occipitomaculata (Northern Redbelly Snake). WAUPACA Co: Sec. 21, T24N, R11E. Spring 1994. Mitch Taylor. MPM 27989. Found dead on road. New county record (Casper 1996); continues documentation of expected range throughout Wisconsin.

Thamnophis sauritus septentrionalis (Northern Ribbon Snake). ADAMS Co: in pothole ca. 5 mi W Briggsville, Sec. 32–34, T14N, R7E. 22 September 1929. Francis M. Uhler. USNM 307855. Verified by Ronald I. Crombie. New county record (Casper 1996); extends range ca. 75 km N of Dane County population and ca. 160 km W of Sheboygan County population for this highly localized species that occurs in isolated populations in Wisconsin.

Acknowledgments.—I thank the collectors named above for their contributions to the Herp Atlas, Jack Puelicher, Allen Young and Robert Henderson for their continuing support, and Ronald Crombie and George Zug for their kind assistance during my visit to the USNM collection.

GREAT GIFT IDEA!

THE WORLD OF TREEFROGS

THE FIRST COMPUTER-AGE WILDLIFE ART

by photographers Jim Bridges & Bob Prince.

A unique, full color, 20X24" image, printed on extremely heavy, high quality, acid free paper. This photographic work of art depicts 38 treefrogs, 15 genera, 32 species of treefrogs from around the world in a single rain forest environment. Each treefrog is approximately life size. A fact sheet listing range, common & scientific names accompanies each image. This marvelous image must be seen to be believed.

To order send $19.95, plus $5.70 S&H*, Lamination $5.00 additional (*outside USA $10.00 S&H)

Not Just Photography, But Art!

BOOK REVIEWS

Amphibien der Westafrikanischen Savanne by Mark-Oliver Rödel. 1996. Edition Chimaira, Frankfurt am Main, Germany. ISBN 3-930612-06-2. Softcover, A5 format (15 x 21 cm), 283 pp., plus 8 color plates. Approx. US $39.95.

ALAN CHANNING
Biochemistry Department, University of the Western Cape
Private Bag X17, Bellville 7535, South Africa
e-mail: Alan@Mbiol.uwc.ac.za

There is little accessible literature on the frogs of West Africa and the title of this work encouraged me to get to grips with the frog fauna of a relatively unknown part of the world. However, I was both impressed and dismayed by this potentially useful book.

Mr. Rödel spent 19 months over a four-year period studying tadpole ecology in the Comoé National Park in northeastern Ivory Coast. This book reflects his own observations and draws on the work of colleagues and the published literature. The resulting product includes information about frogs found throughout the West African savanna belt from Senegal to the borders of Chad and Cameroon.

The text starts with a map of the part of West Africa covered, and with a description of the savanna. Details of geography, geology, and climate are provided for the Comoe National Park, and the major amphibian habitats—rivers, forests, and savannas—are outlined. The text is well researched and clearly written and is illustrated throughout with clear, well-labeled, stippled or line drawings. The production values are less impressive. The first signs of this are the fuzzy photographs included in the introductory section.

The book deals with 51 species under the following headings: synonomy, description, color in life, color in alcohol, call, eggs, tadpoles, habitat, biology, distribution, similar species, and other remarks. German common names are supplied for all the taxa. The list of species covered is comprehensive, not limited to savanna frogs as the title suggests, but also including frogs found in adjacent rain forest and gallery forest. Summaries are provided in German, English, and French.

Although some of the species accounts are based entirely on the literature, the author includes many of his own observations. One example that lays a long-standing error to rest concerns *Hemisus marmoratus*. It is repeatedly and incorrectly reported that the female lays her eggs in a burrow and then digs a tunnel to allow the tadpoles to reach the water. This error was first published in the late 1920s. The author has photographs and records to show that the tadpoles are carried on the back of the female, overland to water. Similar observations have been reported previously, but ignored in favor of repeating the mistakes of well known authors.

The calls are described with reference to published data, and sonograms and oscillograms for 25 species are presented, including the first sonograms of the calls of *Phrynobatrachus latifrons* and *Arthroleptis poecilonotus*. Where sonagrams of west African frogs are given, like *Hylarana galamensis*, no locality data are supplied. In view of the taxonomic confusion surrounding many frog names, with workers in southern, eastern, and western Africa using different names for the same species, and the same name for different species, it would have been valuable if the locality where the recording was made was given with the sonogram.

Many of the species have tadpole mouthparts illustrated by electron micrographs, showing close-ups of labial teeth. Many of the illustrations could have been cropped and enlarged, however, and a hand lens could be handy to see the detail. The tadpole descriptions, with details of development, are thorough and useful. The tadpoles of *Ptychadena schubotzi, Phrynobatrachus latifrons, Hyperolius c. concolor,* and *Afrixalus vittiger* are described for the first time. The extra tadpole details are a reflection of the author's research interests.

The distribution of each species is provided in the form of a list of countries where it has been recorded, with literature citations. The book would have been that much more useful with a map of the distributions in the savanna, as many species are peripheral or restricted to small pockets of specialized habitat, a fact that is lost in the lists of countries.

The final chapter deals with anuran communities in the savanna. It covers survival through the dry season, habitat partitioning, temporal partitioning, reproductive strategies, and tadpole phenology and communities.

The color plates illustrate 39 species, some habitats, eggs of six species, and predators recorded eating frogs. By radio tracking *Hoplobatrachus occipitalis,* the author was able to document that this species is preyed upon by both the Nile monitor, *Varanus niloticus,* and the softshell turtle *Cyclanotis senegalensis.* In addition to the monitor/*Hoplobatrachus* encounter, photos are also provided of a belostomatid water "scorpion" eating *Kassina fusca,* and a fishing spider eating *Hyperolius nitidulus.*

Citations are extensive and accurate, and are one of the strong points of this work. The author has not merely listed the references, but is able to comment on the contents, pointing out errors where they occur. He avoids repeating mistakes from the literature that have been corrected by subsequent authors. It is not often that I have come across such an accurate summary of the literature. I was particularly impressed by the citations from less well-known journals. In particular, the book is a valuable guide to earlier literature.

Some minor errors are present in the text, and the text as a whole could have been improved with careful editing. For example, the author is careless in misspelling *Hildebrandtia* consistently as "*Hildebrantia.*" My dismay is not, however, in the text or illustrations. The author has produced an accurate, readable text that has, however, been less than perfectly assembled into the book. I was initially confused to find figures of one species in the text of another, until I realized that the pages have been bound out of sequence. In my copy the page numbers run 1–48, 53–56, 49–52, 61–64, 57–60, 65–153, (154 is blank), 155–159, (160 is blank), 161–283. It appears as if the text files have been page set from a computer with little memory, as some accounts start on a new page, leaving the previous page half empty, while others run on. Perhaps the DTP program was unable to link files? The poor production and editing is further evidenced by appearance on page 112 of a figure legend *Ptychadena tournieri*, after Guibé and Lamotte 1957, with no accompanying illustration.

Overall, this book will be very useful for anyone wanting an introduction to the literature, or who intends visiting the area. The text is accurate, but the value of the book is marred by amateurish production.

The Neotropical Toad Genus *Atelopus*, by Stefan Lötters. 1996. M. Vences and F. Glaw Verlags GbR, Köln, Germany, 143 pp. US $39.95 (softcover).

RONALD ALTIG

Mississippi State, Mississippi 39762, USA
e-mail: rga2@ra.msstate.edu

What a strange idea—gather all the literature on a single genus of frogs, categorize, summarize, and synthesize it, insert personal thoughts on selected subjects, and then present all of this as a small book (ca. 14 x 21 cm). The result is a great big, immensely annotated version of a CAAR account with a twist—lots of color photographs of garish frogs and their tadpoles presented as a series of montages on glossy paper in the center of the book.

Lötters divided his presentation into three sections. In the checklist (40 pages), each species account includes a brief description followed by various notations (e.g., type locality, range and habitat, citations of illustrations, the holotype designation, a list of materials presented in the original description, and references, including tadpoles). Lists of synonyms within the genus and taxa moved from *Atelopus* to other groups are presented in appendices, and whether one agrees with the taxonomy based on the literature or on Lötters' decisions is not the point—having the information and citations in one source is valuable. The section on biology (33 pages) includes summaries of morphology, musculoskeleton, cytogenetics and molecular systematics, life history and ecology, reproduction, hybridization, and trends in population declines. Three tables summarize the literature on the musculoskeleton, ecological observations, calls, and toxicity. The third section on distribution (10 pages) includes discussions based on political boundaries, physiogeographical regions (several pertinent figures after the appendices), intrageneric sympatry (with a table), and historical zoogeography and evolution. A genus/species index is included, and drawings that follow the appendices include a skull in two views, jaw musculature, eggs of *A. subornatus*, and multiple views of several tadpoles.

The writing is a bit stilted in a few spots but can always be understood. The text is on a coarse, non-glossy paper, and the small print used in parts of the checklist accounts is near the lower limits of easy reading for me. The 70 photographs of frogs (including an extended *A. subornatus* in the middle of an airborne leap), tadpoles, and eggs are of good to excellent quality.

I extended the concept of this book rather loosely into the future and vacillated on the idea of whether a similar book on every genus would be useful. The answer is probably no, but this book on a reasonably small genus of highly variable frogs with a rather voluminous but scattered literature is useful. Also, as we become more and more addicted to electronic literature searches that usually are limited in scope to the last 10 years or less, such a compilation is a ready source of information. The very point of interest often is hidden within a given paper, and Lötter's summarizations allows one to decide if a given reference is important enough to obtain. These summaries would be noteworthy only if the authors were diligent and accurate, and Lötters seems to have been. I cannot imagine a similar volume on large genera like *Rana* or *Bufo* containing the details to make them worthwhile.

In summary, I liked the book as a summary and a resource, and anyone interested specifically in these frogs or the neotropical fauna in general should have it in their library. I do think that one should always go to the primary literature and not cite this or any similar literature compilation.

Amphibien und Reptilien Deutschlands, edited by Rainer Günther. 1996. Gustav Fischer Verlag, Jena. 825 pp. Hardcover. DM 148,00 (approx. US $100). ISBN 3-437-35016-1.

Although there exist many field guides to and popular reviews of the amphibians and reptiles of Europe, comprehensive national herpetofaunal works for individual European countries are rarer. In the case of Germany, the last scholarly treatise on the subject was published by Dürigen (1897) a century ago. Since World War II, many German states (Bundesländer) and municipalities have been the subjects of detailed studies of amphibian and reptile distribution, ecology, and conservation status, but books encompassing Germany as a whole have tended to be superficial and nontechnical (e.g., Blauscheck 1985). After 99 years, finally there is a suitable replacement for Dürigen.

Amphibien und Reptilien Deutschlands began as a collaboration between Rainer Günther and late Hans Schiemenz prior to German reunification, and was intended to cover only the then-German Democratic Republic. Political changes in the country made this goal obsolete and facilitated the expansion of coverage to include the entire Federal Republic of Germany. Günther not only edited the volume, but was an author on virtually every chapter, including all of the species accounts. As a result, the book is characterized by a general uniformity of treatment uncommon in most edited works.

The book begins with a history of herpetology in German-speaking countries by F. J. Obst, and a review of the role of the Ice Age on the development of the middle European herpetofauna (including a review of 31 species represented by Plio-Pleistocene fossils) by G. Böhme. Both classes are introduced with overviews of the systematics and distribution of the German species, including brief summaries of higher order (interfamilial) relations. These sections provide a useful background but are not comprehensive. Well-illustrated keys are provided to eggs and larvae of amphibians and to adults of all species. Key couplets are often long and detailed, a necessity when dealing with groups of very similar species such as the green frogs (*Rana lessonae, R. ridibunda*, and *R.* kl. *esculenta*).

Species accounts are the core of the book, covering all 21 amphibians (seven salamanders and 14 frogs) and 14 reptiles (one turtle, seven lizards, and six snakes) native to Germany. Despite the commonly held view that central and western Europe have long been fully documented herpetologically, it should be noted that three species included in this volume are additions to the fauna since the publication of the latest non-technical book on German amphibians and reptiles (Blauscheck 1985). The additions are *Triturus carnifex* (limited in distribution to extreme southeastern Bavaria), *Lacerta bilineata* (recently elevated to specific status), and *Lacerta horvathi* (first recorded in southern Bavaria in 1990). Each account presents original and review data for German populations of the species. Data derived from extralimital populations are generally noted as such and are stressed only in the cases for which data are lacking for German animals (e.g., *Lacerta horvathi*). Each account is relatively comprehensive covering a review of the history and derivation of the Latin and German vernacular names applied to the species, appearance, color and pattern, size, sexual dimorphism, anomalies, karyotype, distribution, habitat, phenology, movement, retreat sites, population

size, vocalization, reproduction, development, diet, predation, defense, threats, and conservation. Individual accounts range from two paragraphs on *Triturus carnifex* to 42 pages for *Rana temporaria*. There is some variation in the way in which the sections dealing with distribution, population size, and conservation are dealt with. For some species these topics are presented on a general regional basis, in others comments are formally divided by Bundesländer. The maps are based on recent records, chiefly since 1960, with the majority of records since the mid-1970s. Points are plotted onto a standard national map showing major rivers and Bundesländer boundaries and divided into grid cells 11.5 km on a side.

The book concludes with red lists (federal and state) of amphibians and reptiles, references, and an index to German and Latin names. The reference list includes more than 2250 citations, perhaps a record for a book of this nature. Although citations are not as complete as one might like (publishers are not listed for books), the reference list as a whole will prove especially enlightening for North Americans who may be unaware of the diversity of outlets in which German herpetological research has been published.

The text is supplemented by 86 tables and illustrated by 328 black and white figures, maps, charts and graphs, ten black and white plates (mostly associated with the amphibian keys), and 16 color plates with 92 individual photos. The color figures are all adequate or better, although not exceptional. All German species are illustrated in color, usually with the locality of the specimen given. Only in the case of *Triturus carnifex* is an extralimital specimen illustrated. Other color photos include typical habitats, larvae, eggs, mating and defensive behaviors. Black and white photos (habitats, sexual variation, abnormalities, larvae, etc.) are not of uniform quality. Some show depth of field focal problems and others seem to have suffered in the conversion from color slides, with too little or too much contrast. Line drawings are unifomly well executed as are the many graphs, sonograms, pie charts, and histograms.

For most North Americans, language will be a barrier to accessing the information in this book and the amount of detail provided will be overkill. Further, the price will be prohibitive for many herpetologists who do not have active research interests in Europe. However, the book stands as one of the best and most comprehensive country guides available. Indeed, in its specificity and presentation of comprehensive primary literature-based data, *Amphibien und Reptilien Deutschlands* is practically unrivaled. The only comparable recent treatment of European species has been in the ongoing *Handbuch der Reptilien und Amphibien Europas*, edited by Wolfgang Böhme (most recent volume—Böhme 1993) which provides more of an emphasis on morphology (including osteology, hemipenial structure, etc.) and, of course, deals with distribution and biology continent wide. Günther has set an impressive example for authors of other European national herpetofaunal volumes to follow.

Post Bag 4, Mamallapuram 603 104, India

Last reviewed nearly forty years ago by Parakrama Kirtisinghe, the amphibian fauna of the island nation of Sri Lanka (then Ceylon) has increased from 35 species to 53 species. Though well produced for its time, with admirable pen-and-ink sketches, Kirtisinghe's (1957) work is, as expected in tropical countries where biological explorations are incomplete, sadly outdated. As an interim replacement (pending a revision of the fauna now being undertaken by these authors), we are provided with this volume that was brought out during the International Conference on the Biology of the South Asian Amphibians and Reptiles, held in Kandy, Sri Lanka, between 1–5 August 1996. Appropriately, the work honors one of the gifted Sri Lankan naturalists, the late P. B. Karunaratne, collector of many new species of both plants and animals, including some of the herpetological types described by P. E. P. Deraniyagala.

The Introduction contains a short history of explorations in Sri Lanka, a brief review of materials examined, the methods used, an account of Sri Lanka's climate and biogeography (plus a gazetteer with coordinates and altitudes of the 235 sites sampled), and a short (half page) section on amphibian conservation. One is alarmed to read that a decline in precipitation of as much as 25% has taken place during the last century, and few areas of primary forest remain untouched by man.

The book by Dutta (a Lecturer in Developmental Biology at Utkal University, Bhubaneshwar, India) and Manamendra-Arachchi (Research Associate with the Wildlife Heritage Trust of Sri Lanka, WHT, Colombo, Sri Lanka), however, is much more than a field guide. Because it contains synonymies, diagnoses, taxonomic comments, and is lavishly illustrated with both color and black and white photos, it approaches a monograph in technical quality. Born out of a partnership between Dutta (who examined virtually all relevant types as part of a thesis at the University of Kansas; see Dutta 1985) and Manamendra-Arachchi (who did fresh field work to gather new distribution and taxonomic data), the work illustrates all taxa currently recognized from the island (except the enigmatic *Nannophrys guentheri*, whose taxonomic status is questionable and also, surprisingly, the widespread *Microhyla ornata*) with a color photo and very often, photographs of the types and several non-types, from various localities in the country and sometimes from neighboring India. For most photographs, the captions provide information on size of specimen, location, and museum number. The authors deserve to be commended, not only for gathering a near-comprehensive collection of photos, but also for their industry in providing redescriptions of virtually all species through reexamination of the appropriate type specimens and new collections.

The system of classification of ranids is that proposed by Dubois (1992), while the caecilian accounts are based primarily on the work of Nussbaum and Gans (1980). Each species account includes the currently recognized scientific name, synonymy, including the type locality and present location of the primary type, a diagnosis, description (simple and superficial in terms of general body proportions, webbing of toes, etc.), plus color in life,

taxonomic comments, distribution, etymology, and a list of specimens examined (including localities). Accompanying every species is a small distributional dot map. Other illustrations include the hand and foot of frogs and toads, and sometimes other details of the body, such as drawings of head to show mandibles and cranial crests, and radiographs showing the skeletal system.

The weakest section of the book is the bibliography (as a referee of the manuscript of this work, my comments on the bibliography arrived too late to be incorporated). Presumably the section pertaining to amphibian taxonomy and nomenclature came from Dutta's (1985) unpublished doctoral thesis, although new references on the island's vegetation and biogeography have also been included. Problems include incomplete and sometimes incorrect references; about a third of the citations suffer from one or more of these problems. Future editions will benefit by clearing up these problems, as well as providing more substantial descriptions that have a bearing on amphibian phylogeny, such as osteology, vocalization, musculature, and especially details of larval stages, breeding biology, behavior, and chromosomal data.

The last few pages are adorned with color plates of various species of amphibians of virtually every family found in Sri Lanka, all suspected to be undescribed. Terse descriptions of morphological characters point out how they differ from name-bearing species, and although these await comparison with types of species now considered synonymous with species considered valid, it does indicate that the fauna will grow many fold. The rhacophorids are a group to watch out for, as this is the one most difficult, not only to sample, on account of their often arboreal habits, but also because of their frequent lack of clear external distinguishing features, polymorphism, and their rich but unassessed synonymy.

Issued by the Wildlife Heritage Trust of Sri Lanka, this is a well-produced volume with good printing and the binding appears solid enough to withstand years of use in the humidity of the Sri Lankan rainforests, home of much of the country's biodiversity. The Good Samaritan in the production of this and other high quality publications of the WHT is the Founder of the Trust, Rohan Pethiyagoda, also the Managing Editor of the new *Journal of South Asian Natural History*, and a competent ichthyologist in his own right. The volume bears testimony to what can be achieved by a small group of dedicated naturalists.

To sum up, this fine publication will contribute substantially to reawakening interest in a key indicator group of vertebrates, as well as increasing the accuracy of field and lab identifications. I, for one, look forward to the promised systematic revision of the fauna of this enchanting island.

e-mail: sanderson@uop.edu

When the Russian edition of this book first appeared in 1986, it was a landmark in herpetology in that it was the first work that attempted a revision of all of the gekkonid species of the vast area of the former Soviet Union as well as all of the species outside of the Soviet Union that belong to genera having representatives within that region. In addition, it covered genera such as *Tropiocolotes* and *Carinatogecko*, which occur in immediately adjacent countries. Thus it served as a revision of nearly all of the Palearctic geckos from North Africa to Mongolia. It did, however, exclude a number of genera that occur in areas far from the Soviet Union, e.g., *Stenodactylus* (which had recently been revised by Arnold 1980), *Pristurus* (a genus principally of the Arabian Shield), *Hemidactylus* (a pantropical genus with temperate and subtropical representatives), other genera with expanded digital ornamentation, such as *Asaccus*, *Ptyodactylus*, *Tarentola*, and strictly North African genera, such as *Hemitheconyx* and *Geckonia*. At least one review in English of the Russian edition has been published (Bauer 1987).

Unfortunately, the Russian edition was of limited availability, and limited access to non-Russian speakers (including most western Europeans and Americans, of course). The new edition thus brings this important work to a much wider audience of herpetologists and herpetoculturists. It has been printed on much better (acid-free) paper stock, with improved reproduction of illustrations, including 8 color plates (24 photos, many of which are new for this edition).

The book begins with an editors' preface, an explanation of the circumstances that gave rise to this English edition, differences between the two editions, etc. This is followed by the translator's introduction to the English edition. This section, written by Golubev, is a fascinating account of the original preparation of the work, the difficulties encountered, and the limitations of time, length, and content imposed by the Presidium of the Ukrainian SSR Academy of Sciences. I recommend this section to all readers, but especially to those dissatisfied with aspects of the work. It may not blunt all criticism (nor should it), but it will acquaint many American and European scholars with bureaucratic problems in research and publication that they are fortunate not to face (at least not in the same measure).

Apparently, it was decided at the beginning of the translation process that a revision of the work would not be practicable at this time, and thus only factual errors in the original text were corrected, the translation adhering closely to the Russian text (with necessary changes for rendering it clear in grammatically correct English). An important addition, however, is a supplemental bibliography of important papers on Palearctic geckos published since 1986. These new references are cited in footnotes identified with an asterisk, as the numbered footnotes of the original Russian edition have been retained.

The General Section, which begins the actual text of the book, includes a brief critical review of the prior study of the gecko fauna of the regions covered, materials and methods (including places and dates where field work was undertaken, characters used in systematic studies, ecological and behavioral observations), phylogenetic hypotheses and zoogeographical analysis, and a key to the genera. The bulk of the book is taken up with the Systematic Section, consisting of family (Eublepharidae and Gekkonidae), generic, and species accounts. The Literature Cited section contains 328 references, the Russian titles transliterated into Roman type for this edition, and an additional 53 new references.

In the systematic accounts, all taxa are defined or diagnosed and there are keys to all taxa. The keys that I have tested are workable and satisfactory. For the definitions and diagnoses, only morphological characters are used, and even osteological characters appear only in the family definitions. All taxa are given vernacular names, the English names being direct translations of the Russian names. In each species account, the vernacular and Latin names are typically followed by the type locality, the karyotype (when known), primary synonymy, diagnosis, additional characters useful in identification, holotype (or designation of lectotype or neotype), definition, color and pattern, sexual dimorphism and age variation, distribution, geographic variation, ecology, habitat, and other aspects of natural history, such as response to temperature, daily activity, seasonal activity, shedding, feeding, reproduction, growth rate, natural enemies, and aspects of behavior. Obviously, not all of these categories of information are available for all species, but many species were studied by the authors in the field, others were studied in captivity, and some species have a considerable literature covering natural history. Spot distribution maps are provided for each species, each locality numbered and identified in the map legend. Each species has been photographed. Often there is a photograph of the entire specimen, and in each case, critical areas of the specimen are enlarged, the scale patterns reinforced with pen and ink. Whereas, such illustrations may not be as aesthetically pleasing as many line drawings, the accuracy of representation is reliable. There are also a number of black and white habitat photographs.

The authors examined some 5000 specimens and the book contains a wealth of essential data, which are unlikely to be published again in such detail, in spite of the fact that the details of the original manuscript were much reduced by the constraints imposed by the Presidium. Consequently, this book is going to remain essential for the foreseeable future for all who study Palearctic geckos.

Although Szczerbak and Golubev have clarified much of the confusion concerning the nomenclature of geckos of temperate Asia, and while most of their generic allocations of species have been accepted since their study first appeared in 1986, controversy is bound to remain. Because their generic and subgeneric definitions are based on external morphology and, for the most part, on aggregate similarities rather than on synapomorphies, additional support from other characters and approaches will be needed. Indeed, it is possible to formulate different generic definitions and associations based on external morphology. The details of my own differences from their nomenclature are put forth in my book on Iranian lizards (Anderson, in preparation).

One serious problem, important because it embraces so many Asian species, involves the misapplication of the name *Tenuidactylus* Szczerbak and Golubev, 1984 (type species *Gymnodactylus caspius* Eichwald, 1831), which is a junior synonym of *Cyrtopodion* Fitzinger, 1843 (type species *Stenodactylus scaber* Heyden, 1827), Golubev's footnote on p. 126 not withstanding (see Kluge 1985). I have discussed this with Golubev and he agrees.

The phylogenetic hypotheses set forth in the first section of the book (pp. 16–23) will stir disagreements, again because they are based largely on plesiomorphic characters and because they are not supported by the sorts of cladistic analyses that have become standard in systematics in recent years. By way of example, the genus *Carinatogecko* appears to have been derived from a species group in *Tenuidactylus* (their subgenus *Mediodactylus*), making the latter genus paraphyletic. Similarly, *Agamura* appears to be derived from their subgenus *Cyrtopodion* in their analysis, and "... the genus *Tropiocolotes* is close to the genus *Alsophylax*, especially the subgenus *Asiocolotes*, which, probably, is the ancestral branch for the genus *Alsophylax*" (p. 18). Thus, the more accurate their phylogenetic conclusions, the more extensive will be the necessary nomenclatural changes, eventually. To bring gecko nomenclature into line with current systematic practice, either the paraphyletic "ancestral" genera will need to be more inclusive, or all of the derived taxa will need to be redefined.

I do not mean to be hypercritical here; the taxonomy and methodology employed in this book represents the state of the art of systematic practice in the Soviet Union in the mid-1980s. Further, the broad geographic area covered, the inaccessibility of several regions (e.g, Iran, Afghanistan, Baluchistan, much of the Arabian peninsula) makes the acquisition of fresh material for biochemical and karyotypic studies impossible. Thus, the phylogenetic hypotheses advanced here represent a new starting point for future testing and for a future taxonomy of Palearctic geckos.

I did not read the book with the view of catching typos or trivial mistakes. As explained in the Editors' Preface and the Translator's Introduction, at least six people read the manuscript, in part to catch such errors. Inevitably, some remain, and one which may cause confusion, is the use of *T[enuidactylus]* for *T[ropiocolotes]* on p. 9.

Recently, SSAR has been placing dust jackets on its *Contributions to Herpetology*, of which this book is Vol. 13 of the series. The front of the dust jacket is a drawing by David M. Dennis of the skin of *Eublepharis macularius* upon which the title is superimposed in red. Purists may complain that the money would have been better spent on other aspects of the book. However, part of the success of this series has been the marketing of books to readers outside of the scholarly professional community, and the dust jackets and color plates are intended to enhance the appeal to this larger audience.

There is a growing number of serious herpetoculturists for whom geckos have a particular appeal, and increasingly, these people are investing in the more technical literature concerning the groups of their interest. Many gecko enthusiasts will find this book useful, particularly for the natural history information it contains. Obviously, professional herpetologists who study the systematics of geckos or the herpetofauna of the Palearctic will need this publication in their personal and/or institutional libraries.

PUBLICATIONS RECEIVED

Snakes of Louisiana, by Jeff Boundy. 1997. Louisiana Department of Wildlife and Fisheries, Fur and Refuge Division, P.O. Box 98000, Baton Rouge, Louisiana 70898-9000, USA. 32 pp. Softcover. US $5.00. Available from the Louisiana Dept. of Wildlife and Fisheries, Information Division (address as above).

A short guide designed to deal with common questions regarding snake identification, snake bite, and snake folklore in Louisiana. In addition to general information and a checklist of Louisiana snakes by region of the state, the booklet provides short accounts (common and scientific names, identifying characteristics, habits, and distribution within Louisiana) for each of the native species. Sixty color photos illustrate the 40 species covered.

Verbreitung, Ökologie und Schutz der Gelbbauchunke, edited by Andreas Nöllert. 1996. Naturschutzreport Heft 11(1) [Thüringer Landesanstalt für Umwelt, Postfach 24, D-07727 Jena, Germany]. 325 pp. in two volumes. Softcover. DM 20,00 (approx. US $13.00). ISSN 0863-2448.

A collection of papers on the distribution, ecology and conservation of the discoglossid frog *Bombina variegata* in Europe. The papers were originally presented at a symposium held at the University of Jena in 1995. The 30 contributions in the first volume include papers on a wide variety of topics in ecology, conservation, and population biology as well as reviews of the distribution and status of populations in Germany (10 papers), the Netherlands, Switzerland, Italy, Slovakia and the Czech Republic, Romania, and the former Soviet Union (one paper each). The volume is well illustrated by charts, graphs, maps, and a large number of color and black and white photographs (chiefly of habitats). The majority of the contributions are in German, although six are in English. Each paper is followed by its own literature cited section, and a second volume containing an exhaustive bibliography of *B. variegata* (approximately 1300 titles) is also provided. This publication presents an up-to-date picture of a widespread and variable taxon of special conservation concern.

Sampling Amphibians in Lentic Habitats, edited by Deanna H. Olson, William P. Leonard, and R. Bruce Bury. 1997. Northwest Fauna Number 4, Society for Northwestern Vertebrate Biology, Olympia, Washington. Softcover. 134 pp. US $12.00. Available from Janet Jones, Treasurer, Society for Northwestern Vertebrate Biology, 4820 Yelm Highway SE, Suite B-175, Olympia, Washington 98503, USA.

Here is a straightforward handbook to assist biologists in inventorying and monitoring pond-dwelling amphibians. Although not revealed by the title, the authors state in the Preface that this book is focused on the Pacific Northwest—northern California to British Columbia, and eastward to the northern Rocky Mountains. The authors undertook this project in response to urgent calls for standardized survey protocols, and have responded by enlisting various experts to develop the methodologies, which were then field-tested. The result is an easy-to-use volume, complete with numerous color photographs depicting different wetland habitats, charts, maps, and a list of suppliers of necessary field equipment.

Occupational Health and Safety in the Care and Use of Research Animals, by the Committee on Occupational Safety and Health in Research Animal Facilities, National Research Council, National Academy Press, Washington, D.C. 154 pp. Softcover. US $39.95. ISBN 0-309-05299-8.

A review of animal care management and health hazards associated with the maintenance of animals for research purposes. Although there is little specific to amphibians and reptiles in the book, the basic information and recommendations regarding the appropriate protocols for minimizing health risks to those working with live animals are applicable to any animal care facility. The management of efficient occupational health and safety programs for institutions maintaining animal care facilities is also reviewed. The book is well referenced and includes a subject index.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986–1997, *et seq*. Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA). Individual accounts available separately. Cost: US $0.10/page + postage and handling.

The most recent installment (number 17) in this series is *Urosaurus ornatus*, the tree lizard. This account totals 29 pages in addition to a detailed range map representing over 900 localities and based on ca. 3540 specimens. Axtell provides an in-depth discussion of distribution in Texas, along with information about type localities, geographic variation, and suggestions for future work.

Instructions to Publishers

1. Complete and file one copy of this form with your postmaster annually on or before October 1. Keep a copy of the completed form for your records.
2. In cases where the stockholder or security holder is a trustee, include in items 10 and 11 the name of the person or corporation for whom the trustee is acting. Also include the names and addresses of individuals who are stockholders who own or hold 1 percent or more of the total amount of bonds, mortgages, or other securities of the publishing corporation. In item 11, if none, check the box. Use blank sheets if more space is required.
3. Be sure to furnish all circulation information called for in item 15. Free circulation must be shown in items 15d, e, and f.
4. If the publication had second-class authorization as a general or requester publication, this Statement of Ownership, Management, and Circulation must be published; it must be printed in any issue in October or, if the publication is not published during October, the first issue printed after October.
5. In item 16, indicate the date of the issue in which this Statement of Ownership will be published.
6. Item 17 must be signed.

Failure to file or publish a statement of ownership may lead to suspension of second-class authorization.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA.

All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1997 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

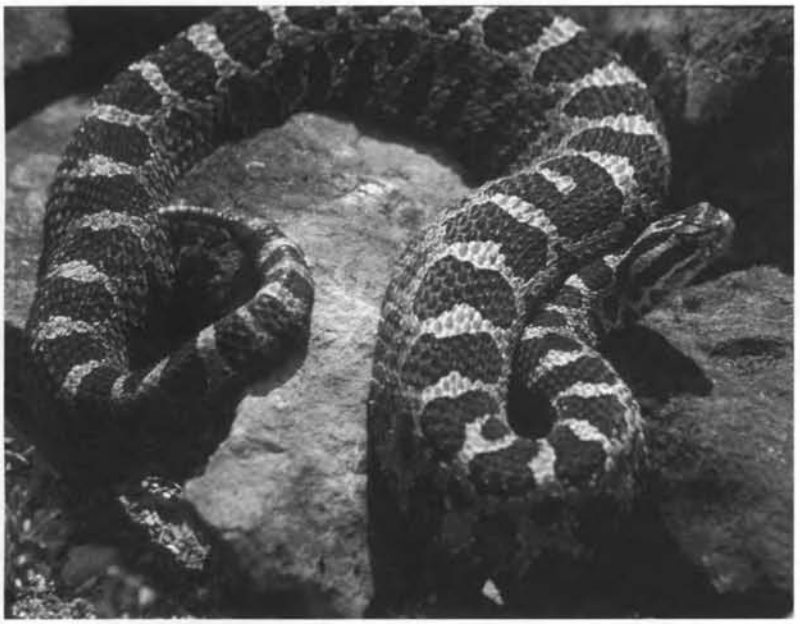
Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).

1998 Annual Meeting
Society for the Study of Amphibians and Reptiles
41st Annual Meeting

together with
American Society of Ichthyologists and Herpetologists
and
The Herpetologists' League



16 – 22 July 1998
University of Guelph, Guelph, Ontario, Canada

The University of Guelph is situated in the Ontario city of Guelph, population 90,000, 100 km (60 miles) west of Toronto. Guelph combines the advantages of a small town atmosphere with the convenience of being located next to a large urban center. The city is rich in 19th century history and architecture. It was founded in 1827 by John Galt in honor of Britain's Royal Family, earning it the moniker the Royal City.

Keynote Address: The keynote address ("The Evolution of Morphological Novelties") will be given by Sharon Emerson, HL's Distinguished Herpetologist for 1998.

Symposium: "Recent Advances in Anuran Communication: A Symposium Honoring Dr. Stan Rand." *Organizer:* Michael J. Ryan, Clark Hubbs Regents Professor in Zoology, Department of Zoology, University of Texas, Austin Texas 78712, USA; e-mail: mryan@mail.utexas.edu. Tel: (512) 471-5078; Fax: (512) 471-9651.

Symposium: "Phenology of Fishes, Amphibians, and Reptiles: Integrating Organism-level and Population-level Perspectives." *Organizers*: Eric Schultz and Kentwood Wells, Department of Ecology and Evolutionary Biology, University of Connecticut, Storrs, Connecticut 06269-3042, USA.

Sistrurus catenatus, the Eastern Massasauga Rattlesnake, is a threatened species in Canada. This specimen was encountered on the Bruce Peninsula in Ontario. Photo by Josh Feltham.

Symposium: "To Freeze or not to Freeze: Amphibians and Reptiles in the Cold." *Organizer:* Kenneth B. Storey, Department of Biology, Carleton University, 1125 Colonel By Drive, Ottawa, Ontario, Canada K1S 5B6; e-mail: kbstorey@ccs.carleton.ca. Tel: (613) 520-3678; Fax: (613) 520-4497.

Symposium: "Herpetology in the Lab and Field: A Symposium in Recognition of the Career of Ronald A. Brandon." *Organizers:* Steve Reilly, Department of Biological Sciences, Ohio University, Athens, Ohio 45701, USA; e-mail: reilly@ohio.edu. Tel: (614) 593-3343, and Ronn Altig, Drawer GY, Department of Biological Sciences, Mississippi State University, Mississippi State, Mississippi 39762, USA. E-mail: rga2@Ra.MsState.edu. Tel. (601) 325-7561.

Contributed Paper and Poster Presentations: There will be concurrent sessions of contributed papers and posters throughout the conference.

Student Paper Awards: Henri Seibert prizes (US $200.00) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. *Refer to details elsewhere in this issue of HR.*

Multimedia Presentations: "HERPETOLOGY OF THE WEST" and "AMPHIBIANS OF THE APPALACHIANS" by David Dennis and Eric Juterbock; "HERPETOLOGICAL NAMESAKES" by Kraig Adler and David Dennis.

The Town Lattice Covered Footbridge on the Speed River was built by 400 timberframers on a design dating back to the 19th Century. Photo courtesy of Guelph Visitor and Convention Services.

Social Activities: General Reception at the University Center Building, SSAR Auction, Picnic, Graduate Student Reception, and Banquet.

Live Exhibit: Live amphibians and reptiles of Ontario will be on display and available for viewing and photo sessions.

Vendors: Books, T-shirts, and equipment for those in the field of herpetology.

Venue: All paper and poster sessions will be held at the University of Guelph campus.

Costs: Pre-registration $170.00 Canadian (approx. US $120) regular, $85.00 CAN (approx. US $60) student, $85.00 (approx. US $60) accompanying person. After April 1, 1998, costs are $220.00 (approx. US $155) regular, $125.00 (approx. US $88) student, and $125.00 (approx. US $88) accompanying person.

Accommodations: The University of Guelph Residences are available to those delegates wishing on-site housing. Delegates may choose to stay in one of our local hotels or bed and breakfasts. Accommodations can be booked through our conference services. For details refer to the Call for Papers or visit our Web site.

Student Travel Grants: Ten travel grants of US $200.00 each will be available for SSAR student members. *Refer to details elsewhere in this issue of HR.*

Travel Arrangements: The official travel agency for the 1998 meetings is Golding Travel Ltd., South City Centre,

Ambystoma laterale-(2)jeffersonianum or LJJ. Several other genomic combinations of hybrid *Ambystoma* are encountered in southern Ontario. Photo by Jim Bogart.

304 Stone Road West, Guelph, Ontario, Canada N1G 3C4. Tel: (519) 836-5100, Fax: (519) 836-1322, e-mail: golding@wat.hookup.net. The recommended airport is Toronto's Pearson International Airport, ca. 100 km (60 mi.) east of Guelph. Shuttle service from the airport is available through "Red Car Service." The conference rate is $29.00 Can. per person each way, payable on the trip; please refer to the form in the Call for Papers. Travel by Rail: there is a twice daily service to Guelph from Toronto (Westbound) and Chicago (Eastbound).

Family Activities: There are many stimulating family activities offered in Guelph and the surrounding area. The African Lion Safari, Marine Land, and St. Jacob's Market are within a short drive of Guelph. Guelph also offers an assortment of historical museums, art galleries, and market places.

Climate: The University of Guelph is located in southwestern Ontario. July is usually warm and dry during the days with temperatures in the mid 20s C (mid to high 70s F). Nights are warm with temperatures around 20°C (low 70s F).

Collecting Permits: The general collection of vertebrates is discouraged at the meeting. Scientific collecting permits are required for the collection of all fish, amphibians, and reptiles in the province of Ontario. Inquiries should be made well in advance and directed to: *Daryl Coulson, Wildlife Biologist, Ministry of Natural Resources, District Office, 605 Beaverdale Road, Cambridge, Ontario, P.O. Box 21048, Canada N3C 2W1. Tel: (519) 651-8159.* Letters to the above address must provide details with respect to the 4 Ws: Who, What, Where, and Why.

Further Details: Contact: *J. P. Bogart, Department of Zoology, University of Guelph, Guelph, Ontario, Canada N1G 2W1. Tel: (519) 824-4120 ext. 6260; fax: (519) 767-1656; e-mail: meeting@uoguelph.ca.* Meeting Announcement and Call for Papers will be mailed to all Canadian, U.S., and Mexican members of SSAR in early December, 1997. Overseas members wishing to receive this information may do so by contacting Jim Bogart at the above address. Please visit the meeting web site at http://www.uoguelph.ca/~ichsherp/ for additional and updated information.

About Our Cover: *Morelia boeleni*

Boelen's Python, one of the most spectacular but also among the rarest pythons, symbolizes the astonishing diversity of New Guinea's snake fauna, recently summarized by Mark O'Shea (1996. A Guide to the Snakes of Papua New Guinea. Independent Publishing, Port Moresby. xii+239 pp.). Lying between distinct faunal regions, New Guinea is home to about 106 species of snakes, including an admixture of both Asian and Australian taxa, as well as species occurring nowhere else. Prominent among the endemics is *Morelia boeleni*, one of the least well-known large pythons. It is restricted to New Guinea, including at least one of the off-shore islands, where all records have come from mid-montane rainforests above 1000 m. O'Shea reports that this is the most protected reptile in Papua New Guinea, although it now is being bred in captivity by European and North American herpetoculturists.

Photographer **Jim Bridges** is known for his attention to detail, typically expending much time and film to capture his subject. Although trained as a commercial artist, and having won awards in both illustration and sculpture, photographic pursuits have gained him widespread recognition. Jim is well known in the herpetological and herpetocultural publishing fields, but the majority of his work has been published in books and non-herp magazines, for such organizations as the National Geographic Society, the National Wildlife Federation, and the Sierra Club.

A burgeoning interest in photography of amphibians and reptiles is reflected by a new herp photography column, written by Bridges for *The Vivarium* magazine, in which he offers tips for taking outstanding herpetological photos. In addition to his skills as a photographer, Jim is adept at electronic imaging techniques, having prepared all of *HR*'s color covers for publication.

Our cover depicts a captive-born, small adult *Morelia boeleni*, photographed in a studio set-up in Florida (see photo, right). A 20 x 24-inch darkroom developing tray was used for a stage. The two large, black triangular objects are Reflectasol Softboxes with studio strobe heads mounted in them. The flash heads, each producing about 200 watt-seconds of light, are powered by an AC power pack on the floor (barely visible under the table). A Canon F-1 camera and 50 mm f3.5 FL macro lens were used to capture this image on Kodachrome 25 film.

SSAR BUSINESS

1997 Annual Meeting: Seattle, Washington

The 40th annual meeting of SSAR occurred from 26 June–2 July 1997 in Seattle, Washington. This year SSAR met jointly with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists on the beautiful campus of the University of Washington. The University, with Ted Pietsch chairing the local committee, served as host to a record number of attendees (>1600). Most of the meeting's events took place at the Husky Union Building.

The unofficial opening of the meetings, the annual meeting of the SSAR Board of Directors, took place on 26 June between 1430 and 2020 h. In attendance for all or most of the Board Meeting were Elected Officers Henry Mushinsky, Darrel Frost, Robert Aldridge, Ellen Censky, John Iverson, Wayne Van Devender, Charlie Painter, and Jim Bogart; Appointed Officers and Editors: Bob Hansen, Steve Corn, Tom Tyning, Rich Seigel; Committee Chairs and Coordinators: Dawn Wilson, George Pisani, Marty Crump, Ken Dodd, Terry Graham; Members: Andy Price, John Moriarty. Others attended to make presentations throughout the afternoon. A summary of business conducted was presented at the Business Meeting (see below).

Presentations

The meetings officially began at 0815 h on 27 June at Meany Hall with opening remarks and announcements from Ted Pietsch. Richard L. McCormick, President of the University of Washington, and Karl Hutterer, Director of the Burke Museum, welcomed all societies to the University. Margaret Stewart, Keynote Speaker and Past President of ASIH, gave an entertaining talk on her years of research entitled "Unfinished Business: What was, What is, and What's yet to be." She was followed by Marty Crump, who delivered HL's Distinguished Herpetologist Lecture on the trials and tribulations of her field work entitled "Frogs: unpredictability, flexibility, and the future."

A record number of papers (851) and posters (201) were presented in 82 oral sessions and three poster sessions. There was one SSAR sponsored symposium "Ecological Processes: Insights from Field Experiments and Natural History: A Symposium Celebrating the Career and Contributions of Margaret McBride Stewart." In addition, SSAR had a round table discussion on "Habitat conservation plans as a replacement for listing under the Endangered Species Act" on 30 June. The SSAR Conservation Forum, Point Counterpoint, was on sustainable use of amphibian and reptile resources and was held on 27 June.

President Henry Mushinsky called to order the 40th Annual Business Meeting of the SSAR at 1510 h in the Husky Union Building Auditorium on Sunday, 29 June. He noted that attendance was low at this business meeting because it had been scheduled at the same time as talks and that this was unavoidable because of the size of the meeting. Mushinsky reported that there was an effort underway to foster more cooperative efforts between the three societies (SSAR, HL, ASIH). The board thought that one way to address this was to have joint committees and that an opportunity presented itself in the Standard and Common Names Committee. Mushinsky said that the committee would be reconfigured to include members representing all three societies. He also made a plea for volunteers for the International Cooperation Program. He asked that anyone who was interested should contact Marty Crump.

There were several people who were recognized for services rendered to the society. They were Joe Collins for his years of service as Standard and Common Names Committee Chairman, Randy Krohmer for his efforts as Translations Editor, Karen Toepfer for her service as Treasurer, Dawn Wilson for chairing the Seibert Award Committee for the Seattle meetings, and Breck Bartholomew for developing an ad for the *Catalogue of American Amphibians and Reptiles*.

Mushinsky also reported that there has been an increase in the number of students participating in the Henri Seibert Student Award contest each year. This year there were 68 participants. Because of the high number of talks, they were grouped into four categories (Systematics, Conservation, Ecology, Physiology & Morphology) and the board had approved one award of $200 for each of these categories.

Treasurer Robert Aldridge reported that the society was in sound financial shape (see report elsewhere), that we had a record number of members (2575), and that renewals were on-track. The board had approved a 1998 budget of $194,642. *Journal of Herpetology* editor Rich Seigel reported that Managing Editor William Parker would be resigning in mid-1998. He welcomed any suggestion for replacement. He also stated that we had the highest number of submissions in the journal's history. He predicted that the backlog would increase to a 12-month lag time by the end of 1998. Allen Press had increased charges for their services and, therefore, the board had increased the budget for the journal to $79,947, but had asked Seigel to contact Allen Press about renegotiating. The editor said that we were moving toward putting the abstracts on the World Wide Web and that anyone who wanted to volunteer to help should contact George Pisani.

The timing of the Business meeting required Secretary Ellen Censky to present the remaining reports. The board approved an increase in the number of pages for *Herpetological Review* from 56 to 64 pages per issue. This will help reduce the backlog of accepted manuscripts. Editor Bob Hansen asked for suggestions from the membership for cover art. Twenty accounts were published in the *Catalogue of American Amphibians and Reptiles*. The board approved a modest increase in the CAAR budget to cover the cost of software and additional color for the accounts. *Contributions to Herpetology* will publish "Biology of the Reptilia, v. 19," edited by C. Gans and A. Gaunt in 1997, and "Lizards of Iran," by S. C. Anderson and "Herpetofauna of New Caledonia and Surrounding Islands," by A. Bauer and R. Sadlier in 1998. Other works in progress for 1998 are "Amphibians of Honduras," by J. R. McCranie and L. D. Wilson, "Biology of the Reptilia, v. 20," edited by Gans and Gaunt, and "Herpetological Illustrations from the Spencer Research Library, University of Kansas," compiled by S. Haines. *Herpetological Circulars* will publish No. 26 "Lineages of Zoo Herpetologists in the United States," by W. Card and J. B. Murphy in late 1997, and "Venomous Snakes: A Safety Guide for Keepers," by W. Altimari is slated for publication in 1998. Volume 1 of *Herpetological Conservation*, "Amphibians in Decline: Canadian Studies of a Global Problem," edited by D. Green, was sent to the printer on 27 May 1997. And finally, the booklet "Grants and Awards for Herpetologists," by J. C. Milam, was produced and is available.

The Conservation Committee sent a questionnaire to zoos and aquaria seeking advice on a conservation brochure. A prototype of the brochure will be ready in the coming year. Thanks to George Pisani and Breck Bartholomew, the Conservation Committee is represented on the SSAR Home Page. Grants-in-Herpetology and the Kennedy Award are announced elsewhere, as are the resolutions. The Student Travel Award Committee made 10 awards of

$200 each. However, because there was no Silent Auction this year, there may not be any awards next year. President Mushinsky made a plea for student members to become involved in this activity as it directly relates to them. In 1996, SSAR contributed $4,000 to the Third World Congress of Herpetology Student Travel Award. This money was combined with NSF money and a total of 18 students were awarded funds for travel to Prague. The SSAR portion was used to fund three non-U.S. members of the society: S. Downes (University of Sydney), J. Melville (University of Tasmania), and J. Rock (University of Otago). This decision was made because the SSAR portion had no restrictions, whereas NSF monies had to go to U.S. students.

Nominations for election to SSAR office for 1998 were announced. President-elect: Victor Hutchison and Harold Dundee; Secretary: Ellen Censky; Treasurer: Robert Aldridge; Director (Class of 2000): John Cadle, Kenneth Dodd, and Julian Lee; Director (Conservation): Dale Belcher, Claudia Luke, and Bern Tryon.

Social Programs

Special events and social programs were numerous and well attended. A display of most species of native amphibians and reptiles from the Pacific Northwest was available for viewing during the course of the meetings at Fisheries Teaching and Research. The display was presented by the Society for Northwestern Vertebrate Biology/Pacific Northwest Amphibian and Reptile Consortium, as well as SSAR and HL. It was sponsored by the University of Washington's College of Forest Resources and Center for Streamside Study, and the Pacific Northwest Herpetological Society.

The social events began the first evening (26 June) with informal gatherings at three local establishments, each of which offered its own unique atmosphere and a wide variety of local microbrews. The next evening (27 June), the General Reception was held in the foyer of Meany Hall. It featured music by the Dan Davison Jazz Combo, by Ray Troll and Russell Wodehouse, and by the "Rappin' Ratfish Brothers," along with generous servings of food and drink. The Graduate Student Reception followed the next evening with food and drink to fill the stomachs of all graduate students attending, and music in the rain by "Salamander" and the Roger Rogers Band. The Salmon Barbecue was held 29 June on the shores of Union Bay at the UW Waterfront Activities Center. The beer flowed, the salmon was barbecued, and the rain held off. The following night the SSAR Auction, with auctioneer Joe Collins, was held in the Husky Union Building. The auction was organized by Mark Adams and a wide variety of auction items had been solicited by Terry Steven-Ayers and others. Lively bidding took place until the closing minutes. The ASIH Banquet was held on the last evening of the meetings in the Husky Union Ballroom.

The annual multi-media event was held in conjunction with the General Reception. As always, "Herpetological Namesakes," by Kraig Adler and David Dennis and "Amphibians of the Appalachians" and " Herps of the West," by David Dennis and Eric Juterbock were well attended. In addition, "Ichthyologists Past and Present," was presented by Brooks Burr.

—Respectfully submitted by Ellen J. Censky, Secretary.

1997 SSAR Resolutions

Honoring Outgoing SSAR Officers and Editors

WHEREAS the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year; and,

WHEREAS they have been therefore instrumental in advancing the Society's goals and furthering its growth as an international scientific society; and,

WHEREAS SSAR is dependent upon the generosity of these persons and those who have gone before them, and is greatly indebted to them for their fine efforts in its behalf;

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles urges these persons not to ride off into the sunset, but rather to continue to be available, with or without official titles, as resources to guide those who follow; and,

RESOLVED FURTHER that the Society offers its most sincere thanks to the following persons who have served in these capacities:

BRECK BARTHOLOMEW—*CAAR* Art/Advertising Volunteer
AARON BAUER—Chair, 1997 Nominating Committee
KURT BUHLMANN—*HR* Section Editor
JANALEE P. CALDWELL—Director
JOSEPH T. COLLINS—*Common and Scientific Names* Coordinator
DAVID CREWS—*Journal of Herpetology* Editorial Board member
WILLIAM E. DUELLMAN— Co-Chair, 1996 Local Committee
ERNIE LINER—Member, 1997 Nominating Committee
EMILIA MARTENS—Member, 1997 Nominating Committee
PAUL MOLER—Director
DOUG RUBY—*Journal of Herpetology* Associate Editor
KAREN TOEPFER—Treasurer
LINDA TRUEB—Co-Chair, 1996 Local Committee
WAYNE VAN DEVENDER—Member, 1997 Nominating Committee
MARVALEE WAKE—Member, 1997 Nominating Committee

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 June 1997 at its Annual Business Meeting.

Special Resolution Honoring Joseph T. Collins

WHEREAS Joseph T. Collins is a founding member of SSAR; and,

WHEREAS over the past 40 years of exemplary service to the Society in myriad capacities, Joe has been among the Society's most influential sources of guidance; and,

WHEREAS Joe has mentored many persons in his distinguished herpetological career; and,

WHEREAS SSAR has matured into the largest professional herpetological society under the guidance of these founders and their able successors;

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles conveys upon Joseph T. Collins special recognition for his years of service.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 June 1997 at its Annual Business Meeting.

Thanking The Local Committee

WHEREAS the University of Washington has provided an excellent setting for this large and diverse joint meeting; and,

WHEREAS Ted Pietsch and members of the Local Committee have overcome myriad logistic obstacles in the course of hosting this meeting; and,

WHEREAS the Local Committee has done a fine job of choreographing the many sessions and events associated with this meeting; and,

WHEREAS the UW beer and beverage policy has added new challenges to the success of certain of these events; and,

WHEREAS the gender semi-segregated shower facilities in certain dorms have provided participants with a renewed sense of togetherness and heightened awareness, enhanced by the strictly diurnal availability of hot water; and,

WHEREAS the well-labelled campus maps, coupled with the often unlabelled pathways and a generally uninformed student body have allowed meeting participants to sharpen their orienteering skills; and,

WHEREAS the outstanding meeting Web site sets a new standard of excellence for Annual Meeting information dissemination, and is evocative of more northern climes in its glacially slow-to-load front page.

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) extends its most sincere thanks to the 1997 Local Committee and others whose assistance contributed to the success of this meeting:

Ted Pietsch (Local Committee Chair), Mike Adams, Beth Babcock, Dianne Baker, Laurie Bauman, Erica Briese, Jeremy Brower, Morgan Busby, Shannon Claeson, Deanne Clare Drake, Tony Han, Ivan Henry, Michael J. Hickerson, Sandra Hines, Greg Hood, Kirt Hughes, Danika Blythe Jauch, Larry Jones, Amy Karpenske, Kathryn Kelsey, Art Kendall, Mike Kinnison, Tom Knight, Shawn Larson, Bill Leonard, Therese Littleton, Andrés López, Mike Mason, Ann Matarese, Michele McGrady, Jay Orr, Bill Pinnix, Susan Picquelle, Rebecca Reuter, Justin Rhodes, Renee Ripley, Todd Ritchie, John Rupp, Cassandra Sandkam, Joe Schumacher, Karin Snelson, Adrian Spidle, Stella Spring, Dan Stearn, Terry Stevens-Ayers, Duane Stevenson, Laura Swaim, Ray Troll, Allison Whitmer, Brian Urbain, UW Extension.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 June 1997 at its Annual Business Meeting.

Resolution Thanking SSAR 1997 Special Event Volunteers

WHEREAS the Annual Auction and Live Display have been features of SSAR annual meetings for many years; and,

WHEREAS these events have added materially to the enjoyment of our members; and,

WHEREAS the SSAR auction has served as a valuable source of revenue for the Society's several programs; and,

WHEREAS the 1997 Local Committee has worked hard to overcome successfully a number of unique obstacles in providing these events this year;

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles expresses its special thanks to these persons for assuring the success of these events this year:

Ted Pietsch (Local Committee Chair), Mike Adams, Larry Jones, Kathryn Kelsey, Terry Stevens-Ayers.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 June 1997 at its Annual Business Meeting.

FURTHERMORE;
WHEREAS a separate resource publication serving as a guide to funding opportunities in herpetology is of patently obvious value to the community, both within and outside the USA; and,

WHEREAS this value extends to all segments of that community including students, zoo personnel, university faculty, etc.; and,

WHEREAS the SSAR board expressed interest in supporting such a resource; and,

WHEREAS Joan Milam volunteered for the task of compiling said resource, and thereafter did so in a timely and professional fashion;

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles expresses its special thanks to Joan Milam for her efforts in behalf of the Society.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 June 1997 at its Annual Business Meeting.

Seibert Award Winners for 1997 Announced

The sixth annual Seibert Awards were presented at the 40th Annual Meeting of the SSAR in Seattle, 25 June–2 July 1997. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meeting, a single award was given in each of the following categories: Systematics (8 eligible presentations), Physiology/Morphology (9), Ecology/Evolution (26), and Conservation (14). All four awardees received a check for US $200 and a book from Academic Press.

The winners.—Systematics: Michele Donovan, Department of Biology, San Francisco State University, "The historical biogeography of the mole salamander, *Ambystoma talpoideum*." Physiology/Morphology: Michael Greene, Department of Zoology, Oregon State University, "Female sex attractiveness pheromones of the brown tree snake (*Boiga irregularis*)." Ecology/Evolution: Sharon Downes, School of Biological Sciences, University of Sydney, "Heat, sex or safety? Using habitat selection experiments to identify a lizard's priorities." Conservation: Sarah Cooper, Department of Biological Sciences, Idaho State University, "Modeling the location of snake dens of the eastern Snake River plain."

Honorable Mention.—Ecology/Evolution: Matthew Flowers, Department of Zoology, Arizona State University, "Sexual color dimorphism in chuckwallas, *Sauromalus obesus*, and implications for sexual selection."

The judges were Dawn S. Wilson, chair (University of Nevada, Reno), Ronn Altig (Mississippi State University), Lee Fitzgerald (Texas A&M University), Anna Graybeal (Field Museum of Natu-

ral History), Tod Reeder (San Diego State University), Paul Stone (University of Central Oklahoma), Wayne Van Devender (Appalachian State University), and Paul Verrell (Washington State University).

SSAR Henri Seibert Award for 1998

The Henri Seibert Award was initiated in 1992 to provide recognition for the best student papers given at the annual meeting of the SSAR. To be eligible, the presented paper must be the results of research conducted by the presenter. The research must have been done while the student was in either an undergraduate or graduate degree program. The presentations will be judged by the SSAR student prize committee. One Seibert Prize of US $200 may be given in each of the four categories: Conservation, Ecology/Evolution, Physiology/Morphology, and Systematics. Please indicate the category to which you are submitting your abstract on the abstract form in the Call for Papers.

Recommendations to Students Entering the Henri Seibert Competition

Be sure you are ready to enter into the competition. Of the 57 papers submitted to the Henri Seibert competition at the 1997 meeting in Seattle, less than half were deemed suitable for competition by the judges. The biggest problem dealt with lack of sufficient data and analyses—many papers reported preliminary results. Students should refrain from submitting preliminary results and forthcoming research to a "Best Student Paper" competition. Preliminary results may be presented in poster form which fosters more discussion than an oral presentation. The following recommendations are intended to aid students to improve the quality of their talks. The criteria presented below are applicable to any talk given at a scientific meeting.

1. Preparing the presentation

A. Audiovisual

- Slides should be clear and legible, even in the back of the room. Use large fonts.
- Avoid the temptation to use a myriad of colors. Stick to a few, easily seen, contrasting colors (e.g., reds are hard to see).
- Use only slides that add to the clarity of the presentation. Several slides showing the same thing tends to bore the audience.
- Time allotted to each slide should be sufficient to allow the audience to absorb the pertinent information. Explain each data slide with regard to axes and content.
- Use a pointer, especially for data slides, but do not overuse the pointer.
- Do not use full data sets in tables. Summarize your data so that tables can be easily seen and comprehended by the audience. Use figures to replace tables when possible.

B. Oral

- Practice, practice, practice! Smooth transitions should occur between slides. NO slide should surprise you by its appearance.
- Speak clearly and use appropriate volume. If you use a microphone, do not turn or walk away from the microphone to address each slide so that your voice fades in and out.
- Often too much time is spent on the methods. Use bullet slides combined with photos (study site/animal, design ...) to work quickly through your methods.

2. Describing your research

A. Design

- Present your research in a larger context by addressing previous studies (choose 1 or 2 to make your point). Relate your data to the knowledge of your field.
- Clearly state your hypothesis(es) and/or objectives up front.
- Flag techniques that are original to your study (i.e., this study is the first to address this question or to use this technique).
- If you deviate from the original plan of the study, be sure to adequately justify your changes or modifications.

B. Summary of Results

- Present your results clearly. Tables with N and P values are fine (but not necessary) if they are readable. Always indicate your sample sizes.
- Indicate the importance of your results. How do they relate to previous studies? Biology in general?

C. Importance of Study

- Summary slides of conclusions (bullet slide) are helpful in tying together many results.
- State the importance of your study and how your research has added to knowledge of the subject presented. Are your results generally applicable to larger biological questions?

D. Miscellaneous

- No one works in isolation. Be sure to acknowledge (briefly) collaborators and funding agents. This can be done at the beginning or end of the talk, but it may take away from the final message if done at the end.
- Try very hard to limit yourself to 12 minutes. Ability to handle questions is part of the judging criteria. Failure to leave time for questions can leave the audience frustrated.
- Again, practice your talk many times before giving it. You will find that the more you practice, the more confident you will feel and the more polished your talk will be.

Artwork and Slides Wanted for *HR*

We are seeking high quality illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90 mm wide column. Of particular interest are drawings of material for which locality data or museum catalogue numbers are available; this information should be included with the drawings. Original art (or good quality photocopies) should be packaged to ensure safe delivery and sent to the Editor.

Also, we are interested in evaluating outstanding color slides of amphibians and reptiles for possible use on future *HR* covers. If you would like your work to be considered, please contact the Editor prior to shipping any slides. Postal and e-mail addresses are listed on the inside front cover.

SSAR Student Travel Awards Call for Applications

Awards of US $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author (or co-author, see below) of a paper or poster to be presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that states: he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Student Travel Awards Committee are excluded from applying for a travel award.

APPLICATIONS MUST BE POSTMARKED BY 15 MAY 1998. Award recipients will be notified by 1 June 1997 and award checks will be disbursed at the meeting. Direct requests for information to: Todd Esque, U.S. Geological Survey, Biological Resources Division, 345 East Riverside Drive, St. George, Utah 84790, USA; tel. (801) 688-3215; e-mail: esque@usgs.gov. Please list the subject for any such e-mail as: SSAR Travel.

SSAR Student Awards Fund-raiser: 1997 Results and Call For 1998 Donations

Thanks to the many generous donations from several individuals to the 1996 silent auction in Seattle, the SSAR Student Travel Awards Committee (SSAR STAC) awarded ten US $200 travel grants to the following individuals: Kyle Ashton, Russell Bodie, Marguerite Butler, Melissa Dills, Maureen Kearney, William Lutterschmidt, Jeff Parmelee, Lora Smith, Tracey Tuberville, and Allison Welch. In 1997 the SSAR Student Travel Awards Frameable Art Silent Auction was not held, but the SSAR STAC is grateful to Joe Collins for auctioning donated materials on behalf of the Student Travel Awards.

The SSAR STAC announces the Fourth Annual Frameable Art Silent Auction to be held at the 1998 SSAR meeting in Guelph. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: Todd Esque, U.S. Geological Survey, Biological Resources Division, 345 East Riverside Drive, St. George, Utah 84790, USA; tel. (801) 688-3215; e-mail: esque@usgs.gov.

Directory of Herpetologists

SSAR, The Herpetologists' League, and the American Society of Ichthyologists and Herpetologists are preparing to issue a joint directory of herpetologists. This will be done by merging the membership lists of the three societies. If for some reason you DO NOT wish to be listed in the directory, please tell us by e-mail (Harold Dundee <dundee@plato.museum.tulane.edu>) or by snail mail (Dr. Harold A. Dundee, Tulane University Museum of Natural History, Belle Chasse, Louisiana 70037-3098, USA. Fax: (504) 394-5045). The default option is to list everyone.

Also, if you receive journals at your home address, but wish instead to have an institutional address published, please advise as above.

Journal of Herpetology: On-Line Abstracts

As a new service to our readers, the *Journal of Herpetology* is pleased to announce that starting with the March 1998 issue, the complete abstracts of major papers will be placed on-line on the SSAR Home Page on the World Wide Web (URL: http://falcon.cc.ukans.edu/~gpisani/publink.html). Abstracts will be available about five months prior to publication, and will remain on-line until the papers are published. We will provide the e-mail and "snail mail" addresses with the abstract, and interested readers are asked to contact the author for a pre-print of the full paper. If there is sufficient interest in this service, we also will begin providing brief summaries of Shorter Communications as well.

Please direct any questions or comments on this service to: *Richard. A. Seigel, Editor, Journal of Herpetology, Dept. of Biological Sciences, Southeastern Louisiana Univ., Hammond, Louisiana 70402-0736, USA. E-mail: rseigel@selu.edu.*

Needed: Slides of Herpetologists

The audiovisual program "Herpetologists Then and Now," first shown at the 1982 SSAR meeting in Raleigh, has been seen at many meetings in the US, Canada, and the UK in subsequent years and has undergone several revisions. The producers, Kraig Adler, David M. Dennis, and J. Eric Juterbock, plan another revision for 1998 and appeal for photographs of our colleagues or of herp activities, etc. (Sources of photos are not revealed.) Ideally, we want color slides (copies that we can keep) or, where necessary, black-and-white prints that we can make into slides. Please provide data (names, places, etc.). Humorous photos are especially desirable.

Materials should be sent to: *David M. Dennis, General Biology Annex, The Ohio State University, 1791 Neil Avenue, Columbus, Ohio 43210, USA (office phone: 614-292-1371).*

NEWSNOTES

Southwestern Research Station Positions And Grants For 1998

VOLUNTEERS—Approximately 30 volunteer positions are open in 1998 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, contact: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 1998. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin March 15, 1998, through September 1998. Five-day week; salary $210/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

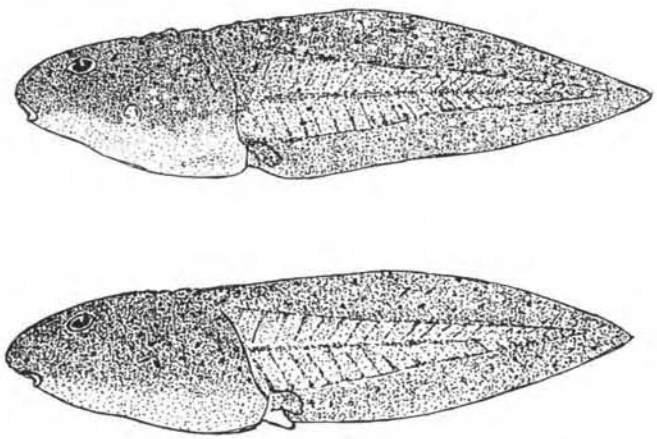
Position Available: Curatorial Internship

The Wildlife Conservation Society, based at the Bronx Zoo in New York, is a world leader in the preservation of wildlife through captive management, field studies, and creation of reserves. The Department of Herpetology promotes conservation through administration of Species Survival Plan and studbook programs, development of reintroduction protocols in conjunction with our Wildlife Health Sciences division, field studies, an innovative exhibition of reptiles and amphibians, the management of a 750-specimen living collection, an interpretive program including the Reptile Conservation Station, and collaboration with local, state, federal, and international wildlife agencies.

We are seeking applicants for the position of curatorial intern to begin in January 1998. The program will include participation in the above mentioned activities. The curatorial intern would carry the title Herpetologist, and is recognized as a career path to a curatorship.

Requirements: Advanced degree in zoology, ecology, conservation biology, or related field with demonstrated interest in herpetology. Must have excellent communication, computer, interpersonal, and report writing skills. Please submit resume to: *Department of Herpetology, Wildlife Conservation Society, Bronx Zoo, Bronx, New York 10460-1099, USA.*

Contemporary Herpetology, a New Electronic Journal



On 1 January 1998, *Contemporary Herpetology* (*CH*), a peer-reviewed electronic journal devoted to herpetology, will go online (URL: http://vmsweb.selu.edu/~pcsd4805/) with the following articles:

> A key to the anuran larvae of the United States and Canada, by Ronald Altig, Roy W. McDiarmid, and Kimberley A. Nichols.
>
> Taxonomic status of the Wyoming toad, by Hobart M. Smith, David Chiszar, and Joseph T. Collins.

We are currently soliciting papers, which can be submitted to managing editor Travis Taggart (ttaggart@selu.edu) via e-mail. *CH* will publish articles covering all aspects of herpetology, including ecology, ethology, systematics, conservation biology, and physiology. *CH* also will publish monographs, points-of-view, and faunistic surveys of poorly-known areas. *CH* will not publish herpetocultural or anecdotal papers. Internet technology provides publication capabilities that were either impossible or expensive in previous media, including full-motion video, full-color digital photography, computer simulations, and audio playback. For questions about *CH*, contact the editor, Joe Slowinski (jslowins@cas.calacademy.org; tel. 415-750-7041).

Graduate and Post-Graduate Research Grants

The Biological Research Station of the Edmund Niles Huyck Preserve offers grants (max. = $2500) to support biological research that utilizes the resources of the Preserve. Among the research areas supported are basic and applied ecology, animal behavior, systematics, evolution, and conservation. The 2000-acre Preserve is located on the Helderberg Plateau, 30 miles southwest of Albany, New York. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10 and 100-acre lakes, and several waterfalls. Facilities include a newly expanded laboratory building, library, collections, and houses/cabins for researchers. Deadline: 1 February 1998. Application material: *Dr. Richard L. Wyman, Executive Director, E. N. Huyck Preserve and Biological Research Station, P.O. Box 189, Rensselaerville, New York 12147, USA.*

Rana catesbeiana (Bullfrog), top, and *Rana aurora draytonii* (California Red-legged Frog), bottom. USA: California: San Diego and Riverside counties, respectively. Illustrations by Dan Holland.

LEGISLATION & CONSERVATION

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. Please direct all communications to the Section Editor.

Colombia: The Colombian government announced in July that the Orinoco crocodile (*Crocodylus intermedius*) is "in danger of extinction" in its country. The announcement marks the first survey of these crocodiles in Colombia since the mid 1970s. The Orinoco crocodile is restricted to the lowland drainages of the Orinoco River in Venezuela and Colombia and is one of the seven most endangered crocodilians in the world (1992 IUCN/SSC Crocodile Action Plan). Initial declines were the result of commercial overexploitation from the 1930s through the 1950s; however, most commercial hunting ceased by the 1960s because of scarcity of animals. Habitat destruction, egg collection, illegal hunting, and competition with the spectacled caiman (*Caiman crocodilus*) all have been listed as causes for the species' lack of recovery in the past 20–30 years (Arteaga et al. 1994, in *Crocodiles: Proceedings of the 12th working meeting of the IUCN/SSC crocodile specialist group.*). Orinoco crocodiles are currently protected under CITES Appendix I. In addition, Venezuela has a conservation plan that includes headstarting and reintroducing crocodiles into two areas of protected crocodile habitat. With the forthcoming plan to protect Colombia's remaining populations, the future of *C. intermedius* looks increasingly optimistic.

USA: US Fish and Wildlife Service: The revised Notice of Review names 306 species that may warrant protection under the Endangered Species Act. The 1997 Notice contains 71 plants and animals proposed as endangered, 28 proposed as threatened and 207 candidates for proposal. The Notice is published primarily to inform potential investigators of the need for information concerning taxa in greatest jeopardy. Specifically, the Fish and Wildlife Service requests information: 1) indicating that a taxon should be removed from the Notice, 2) indicating that a taxon that is not on the Notice should be included, 3) recommending an area as critical habitat for a candidate taxon or that protection of critical habitat would not be prudent for a taxon, 4) documenting threats to any of the included taxa, 5) describing the immediacy or magnitude of threats facing candidate taxa, 6) pointing out taxonomic or nomenclatural changes, 7) suggesting appropriate common names, and/or 8) noting any mistakes such as errors in historical range. The following amphibians and reptiles are included in the Notice: *Ambystoma californiense* (= *A. tigrinum c.*; candidate), *Bufo boreas boreas* (southern Rocky Mountain population; candidate), *Rana chiricahuensis* (candidate), *Rana lutiventris* (Wasatch Front, West Desert, and Great Basin populations; candidate), *Rana pretiosa* (West Coast population; candidate), *Anniella pulchra nigra* (proposed endangered), *Clemmys muhlenbergii* (northern populations, proposed threatened), *Graptemys caglei* (candidate), *Kinosternon sonoriense longifemorale* (candidate), *Masticophis lateralis euryxanthus* (proposed endangered), *Nerodia sipedon insularum* (proposed threatened). The full Notice of Review as well as contacts for interested persons or organizations can be found in the *Federal Register* Vol. 62, No. 182, pp. 49398–49411 (September 19, 1997).

CITES: The tenth regular meeting of the Conference of the Parties (COP10) convened June 9–20, 1997 in Harare, Zimbabwe to consider proposed amendments to CITES. The following amendments concerning trade in amphibians and reptiles were adopted (proponent in parentheses): Order Testudinata: *Callagur borneoensis*—inclusion on Appendix II (Germany); Order Crocodylia: *Caiman latirostris*—transfer of Argentina population from Appendix I to II for ranching (Argentina); *Crocodylus niloticus*—maintenance of Madagascar and Uganda populations on Appendix II for ranching (Madagascar, Uganda); *Crocodylus niloticus*—annual export quota for 1998 through 2000 of 1000 skins and 100 hunting trophies (Tanzania). Additional information can be found in CITES update #55 (August, 1997).

MEETINGS

Third World Congress of Herpetology 2–10 August 1997, Prague, Czech Republic

ZBYNEK ROÇEK
Department of Paleontology, Geological Institute, Academy of Sciences
Rozvojová 135, 165 00 Praha 6 - Suchdol, Czech Republic
e-mail: Rocek@gli.cas.cz

and

MARVALEE H. WAKE
Department of Integrative Biology and Museum of Vertebrate Zoology
University of California, Berkeley, California 94720-3140, USA
e-mail: mhwake@socrates.berkeley.edu

The World Congress of Herpetology, an international non-governmental organization founded to support herpetology worldwide, held its third congress last August in Prague, Czech Republic. Previous congresses were held in Canterbury, England and Adelaide, Australia. These congresses are generally regarded as the most representative meetings of herpetologists both for number of nationalities (more than 850 representatives from 58 countries were in Prague) and scope of presented topics. Thus, they provide a platform for meetings and exchange of ideas with specialists from other fields of herpetology who usually hold separate meetings. Interdisciplinary approaches to problems through wide-ranging discussions are one of the most beneficial aspects of such large meetings. Bearing this in mind, the congresses are open, according to the Statutes of the WCH, to anyone who works in any field of herpetology or is interested in herpetology, regardless of whether they deal with extant or extinct taxa.

Two directions were followed in the course of preparation of the scientific program. The organizers preferred that the congress should be conducted along long-standing principles for scientific meetings of this kind, i.e., to enable people to present the results of their research and to discuss them with others. A free choice of what to present can reflect the range of topics and the state that each pertinent field has reached since the previous congress. Therefore, the main part of the congress consisted of contributed papers arranged in topical units (sessions in the case of talks, and topical arrangements in the case of posters). In addition, there were specialized symposia and round tables organized in advance by people who wanted to promote discussions of particular topics. The organizers' requirement was that contributors not give just review presentations; they therefore rejected abstracts that did not contain new and original results. On the other hand, they accepted some non-orthodox papers and presentations that criticized some routine and deeply-rooted approaches and methods (e.g., cladistics, model animal approaches, etc.).

The scientific program resulted in a very colorful and multilateral presentation of a wide range of views, but at the same time showed a few dominant fields of herpetology in which herpetologists' interests worldwide have been focused during the last decade of this century.

Undoubtedly, the principal arena of interest was the global decline of amphibian and reptile populations and related topics (impact of human activities, environmental contaminants and other possible causes of the declines, conservation biology, strategies for conservation, etc.). Of six simultaneous sections running over the whole week, one was devoted nearly completely to this topic (76 talks, plus a half-day workshop on conservation of Europe's threatened herpetofauna organized by the Societas Europaea Herpetologica Conservation Committee and the IUCN Species Survival Group for European Herpetofauna). Similar topics were covered by 27 posters. This, together with contributions dealing with conservation biology as a "side product," represented about 15% of all 773 papers submitted to the congress. Most of these presentations documented the degree of decline; only a few of them proposed methods and strategies to deal with declines. General concern about future developments in conservation and maintenance of the herpetofauna also was expressed in one of the resolutions addressed to many supra-national and national organizations; it specifically supported the work and perspective of the Declining Amphibian Populations Task Force.

Another dominant topic represented in the congress was evolution, associated with phylogeny and systematics. Several sessions and symposia were held during the congress that fit into this field, such as one-day sessions on "Evolution and Systematics of Anura" and "Evolution of Caudata," a one-and-a-half day session on "Evolution and Systematics of Reptilia," and one-day sessions on "Evolution and Systematics of Snakes" and the more specialized "Phylogeny and Systematics of the Viperidae." Also, this part of the congress comprised about 15% of the total number of contributions, including posters.

Predictably, a number of evolutionary contributions were based on fossil material. However, paleoherpetology in general was not, contrary to expectations of the organizers, well represented in the congress. This resulted in short (but high quality) sessions on "Paleozoic Amphibia" and "Early Reptiles," and a half-day symposium on "Mesozoic Amphibians and Reptiles." About a dozen contributions dealt also with the post-Mesozoic fossil record of amphibians and reptiles. Nevertheless, a relatively low number of paleontological contributions can be interpreted as a fact that the wall separating paleo- and neo-herpetologists still exists, and the fact that the object of study is a fossil is more significant than that it is an amphibian or reptile.

Another "strong" field represented in the congress was ecology, especially population ecology of amphibians (altogether nearly 100 presentations). Worthy of mention in this respect were also symposia on "Climate Variation and its Impact on Herpetofauna," "Temperature and Sex Determination in Reptilia," and "Sea Turtles: Biology, Ecology, Management."

There were many other topics represented to a lesser degree in the congress, such as accounts of regional herpetofaunas given in a session entitled "Zoogeography of Amphibia and Reptilia" and a similar part of the poster exhibit; they comprised about 50 presentations (about 7% of all papers submitted). However, one must also add papers presented in the symposium "Africa—The Neglected Continent: Biodiversity and Biology of the African Herpetofauna," and others.

The scope of topics also included behavior of reptiles, calling behavior in Amphibia, growth and development (e.g., the symposium on "Neonatology of Reptiles: Character States Expressed Most Strongly Within the First Year of Life"), physiology, amphibian and reptilian venoms, reproduction, chromosomal studies, parasitology, breeding in captivity, and methods and approaches. Some pre-organized symposia (such as "The Eurasian Green Toad as a Model Species for Studies in Evolutionary Biology" and "Plasticity in Amphibian Reproduction, Development, and Evolution") covered several topics already mentioned.

Large international meetings are also social events, and local organizers usually want to present typical cultural features of the host country. The Czech Republic is famous for its high-quality beer and classical music. Consequently, one evening gathering was held in the oldest brewery in Prague, dating back to 1496. Another night was spent on board a steamer on the Vltava River, which provided an opportunity to see the beautiful panorama of the city and its castle. However, the real highlight of the social program was the concert of old Czech music in the most famous concert hall in Prague. Long-lasting applause brought the musicians back to the stage; after the concert, people did not want to leave the concert hall, and stayed a long time on the main staircase talking in the warm summer night.

The business program included the WCH Business meeting, the International Herpetological Committee meeting and, because the European Herpetological Society was a co-organizer of the congress, also the 9th Ordinary General Meeting of Societas Europaea Herpetologica. In addition, several other committees, boards, and organizations held meetings at the congress site. Three

Herpetology '97

Abstracts of the Third World Congress of Herpetology

edited by Zbynek Roçek and Scott Hart

THIS NEW PUBLICATION CONSISTS OF MORE than 760 abstracts, submitted by authors to the Third World Congress of Herpetology. Authors from every continent and virtually all fields of herpetology are represented. Each abstract includes author's mailing address, key words, and in many cases, information regarding where the paper will be published in full. The book also includes topically arranged contents, as well as author and subject indexes. Hence, the book provides a good review in contemporary herpetology, especially valuable to those unable to attend WCH-3 in Prague. Moreover, because it is likely that not all presented papers will be published, this book makes available a great amount of valuable information to the scientific community.

Copies (nearly 260 pages; the free Programme Book is included) may be purchased from the Congress Secretariat (c/o Czech Medical Association, J.E. Purkyne, P.O. Box 88, Sokolská 31, CZ 120 26 Praha 2, Czech Republic. Fax: ++420 2 294610, e-mail: lon@czechmed.anet.cz). The price is 600 CZK (approximately US $18) plus handling and postage. Discount price is offered when more than 10 copies are purchased at once.

very attractive bids for the Fourth World Congress of Herpetology were proposed and are now being considered by the Executive Committee.

In sum, the congress reflected the current state of herpetology, and enabled the assessment of advances attained in this field of science, and its current and possible future trends. Those who were not able to be in Prague at least can have the book "Herpetology '97," which includes approximately 770 abstracts with the addresses of authors and a Subject Index. *(See ad elsewhere in this issue of HR for ordering details.)* Those who desire to become acquainted with the WCH documents (report of the Secretary General, Treasurer's report, report of the Congress Director, WCH-3 resolutions, etc.) are invited to visit the WCH Web page at: http://www.gli.cas.cz/herpet. The site originally contained information concerning WCH-3, but will be gradually changed into a source of information about current developments in the World Congress of Herpetology, until organizers of the WCH-4 open their own Web page.

Meetings Calendar

20–21 March 1998—Midwest Declining Amphibians Conference. Joint meeting of the Great Lakes and Central Division Working Groups of the Declining Amphibian Populations Task Force. Hosted by the Milwaukee Public Museum, Milwaukee, Wisconsin, USA. Contact: Gary S. Casper, Vertebrate Zoology Section, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA. Tel. (414) 278-2766; fax (414) 278-6100; e-mail: gsc@uwm.edu. Meeting Web site: http://www.mpm.edu/collect/vertzo/herp/DAPTF/Midwest.html.

1–3 June 1998—Biodiversity and Conservation of Amphibians and Reptiles of Tropical Forests: An International Symposium. Hanoi, Vietnam. Contact: Natalia Ananjeva (St. Petersburg, Russia), e-mail: nbanorus@glas.apc.org.

12–15 June 1998—Highlands Conference on Plethodontid Salamanders, Highlands Biological Station, Highlands, North Carolina, USA. To be placed on the mailing list, or to up-date your address, please send your name, address, and numbers (phone, FAX, e-mail) to: Plethodontid Conference, Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA, or send an e-mail message to Judy Hill at: JHILL@wpoff.wcu.edu. Additional information: http://www.wcu.edu/hibio.

26–27 June 1998—22nd Annual Meeting of the International Herpetological Symposium, Inc., Holiday Inn-Cincinnati Airport, Cincinnati, Ohio, USA. Contacts: Stan Draper, IHS Secretary, P. O. Box 16444, Salt Lake City, Utah 84114-0444, USA; e-mail: sdraper@npsp.com; or Pete Strimple, Liaison Committee Chair, 5310 Sultana Drive, Cincinnati, Ohio 45238, USA; tel. (513) 451-2392; e-mail: pds0404@aol.com.

16–22 July 1998—41st Annual Meeting, Society for the Study of Amphibians and Reptiles; 46th Annual Meeting of The Herpetologists' League; 78th Annual Meeting, American Society of Ichthyologists and Herpetologists. Hosted by the University of Guelph, Guelph, Ontario, Canada. *Refer to meeting announcement in this issue for details.*

1–5 September 1998—Third International Asian Herpetological Meeting, Almaty, Kazakhstan. To receive the First Announcement and Preliminary Registration Form, please contact one of the meeting organizers: Dr. Tatjana Dujsebayeva, Department of Biology, Kazakh State University, Al-Farabi Prospect, 71, Almaty, 480078, Kazakhstan; tel. (3272) 472677; fax (3272) 472609; e-mail: zool@plague.almaty.kz; Dr. Natalia Ananjeva, Department of Herpetology, Zoological Institute, Universitatskaja nab., 1, Saint-Petersburg, 199034, Russia; tel. (812) 2180711; fax (812) 2182941; e-mail: anb@zisp.spb.su; or Dr. Theodore Papenfuss, Asiatic Herpetological Research, Museum of Vertebrate Zoology, University of California, Berkeley, CA 94720, USA; tel. (510) 642-3567; fax (510) 643-8238; e-mail: asiaherp@uclink2.berkeley.edu.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, P.O. Box 58355, Salt Lake City, Utah 84158-0355, USA; e-mail: herpbooks@sisna.com. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are being listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Amphibian Community Ecology

Semlitsch et al. present results of 16 years of monitoring the amphibian community at a natural pond in South Carolina. Pond hydroperiod was found to be a primary source of variation in community structure. Temporal variation may favor the reproductive success of different species in different years, with juvenile production being episodic over time. Larval competition and salamander predation also have a detectable influence, but the strength of their influence on the success of species is mediated by pond hydroperiod. (Reprints available from the Savannah River Ecology Lab, P.O. Drawer E, Aiken, South Carolina 29802, USA.)

SEMLITSCH, R. D., ET AL. 1996. Structure and dynamics of an amphibian community: Evidence from a 16-year study of a natural pond. Pp. 217–248, *in* Long-term Studies of Vertebrate Communities. Academic Press.

Salamander Names

By action of the International Commission on Zoological Nomenclature (ICZN), the plethodontid salamander genus *Hydromantes* was placed on the Official List of Generic Names in Zoology with the type species being designated as *Spelerpes platycephalus*. This designation should prove satisfactory to both European and American herpetologists who have long had to deal with a confusing history of taxonomic priority with the generic name of these salamanders.

In other action by the ICZN, Hemidactyliini Hallowell, 1856, was conserved as a family-group name,while the older, but rarely used, Mycetoglossini Bonaparte, 1850, was suppressed.

ANONYMOUS. 1997. Opinion 1866: *Hydromantes* Gistel 1848 (Amphibia, Caudata): *Spelerpes platycephalus* Camp, 1916 designated as the type species. Bull. Zool. Nomencl. 54(1):72–74.

ANONYMOUS. 1997. Opinion 1873. Hemidactyliini Hallowell, 1856 (Amphibia, Caudata): conserved. Bull. Zool. Nomencl. 54(2):140–141.

Plethodontid Salamander Phylogeny

Jackman et al. analyzed sequence data for 555 bp of the mitochondrial gene cytochrome *b* in plethodontid salamanders representing the tribes Bolitoglossini and Plethodontini. They also analyzed 37 morphological characters. There was little conflict between the morphological and DNA data sets. Among the important findings are support for the monophyly of the supergenera *Hydromantes* (inclusive of both American and European species) and *Batrachoseps*, and of a sister-group relationship of *Batrachoseps* and the supergenus *Bolitoglossa*. They further demonstrate conclusively the monophyly of the Bolitoglossini. Their work also provides solid evidence for the independent evolution of highly projectile tongues: *Hydromantes* has a tongue specialized for distance, while that of the supergenus *Bolitoglossa* is specialized for speed.

JACKMAN, T. R., G. APPLEBAUM, AND D. B. WAKE. 1997. Phylogenetic relationships of bolitoglossine salamanders: a demonstration of the effects of combining morphological and molecular data sets. Mol. Biol. Evol. 14(8):883–891.

Wake summarizes recent, unpublished research involving protein variation and mitochondrial DNA sequences for salamanders of the *Ensatina eschscholtzii* complex, a well-known "ring species." These new data reveal that the complex includes a number of geographically and genetically distinct units that are at or near the species level. The complex is geologically old and apparently has undergone instances of range contraction, isolation, differentiation, and then expansion and secondary contact. This work nicely illustrates the difficulty of making taxonomic decisions in a complex exhibiting the full array of intermediate conditions between well-marked species and geographically variable populations.

WAKE, D. B. 1997. Incipient species formation in salamanders of the *Ensatina* complex. Proc. Natl. Acad. Sci. USA 94:7761–7767.

Desert Tortoise Health

The Arizona Game and Fish Department recently published a report by Dickinson et al. in which two Sonoran populations of desert tortoises were surveyed over a five-year period to determine their health status in comparison to Mojave Desert populations. Blood, nasal aspirate, choana and cloacal swabs, and fecal samples were collected repeatedly from 36 tortoises for comparative blood chemistry, microbiological, and parasitological assessments. Among the more disturbing results was the finding of *Mycoplasma agassizii* in three Sonoran tortoises. This *Mycoplasma* is the causative agent of upper respiratory tract disease (URTD), which has been blamed for massive die-off of Mojave populations of *Gopherus agassizii*.

DICKINSON, V. M., J. L. JARCHOW, AND M. H. TRUEBLOOD. 1996. Health studies of free-ranging Sonoran Desert Tortoises in Arizona: A final report. Arizona Game and Fish Department Technical Report No. 24, Phoenix, vi + 79 pp.

DNA Content and Techniques

Murphy et al. discuss the use of flow cytometry of blood as a tool for rapidly sorting individual specimens on the basis of cellular DNA content. In a previous paper, the authors found that flow cytometry enabled them to identify both cryptic sympatric and allopatric species of Vietnamese ranid frogs. Protocols for preparation of freezing solution, field procedures, preparation of reference standards, and flow cytometric analysis are among the topics discussed.

MURPHY, R. W., ET AL. 1997. Flow cytometry in biodiversity surveys: methods, utility, and constraints. Amphibia–Reptilia 18(1):1–13.

MacCulloch et al. examined the diploid nuclear DNA content of 72 species of amphibians and reptiles using flow cytometry. The authors found amphibian DNA content was generally greater than that of reptiles, but greater intraspecific variation occurred in reptiles. They were also able to identify several cryptic species among morphologically similar specimens. The use of flow cytometry in DNA content studies is discussed.

MACCULLOCH, R. D., D. E. UPTON, AND R. W. MURPHY. 1996. Trends in nuclear DNA content among amphibians and reptiles. Comp. Biochem. Physiol. 113B(3):601–605.

Jockusch examined the relationship among two life history traits—egg size and embryonic developmental time—and genome size in 15 species of plethodontid salamanders. There was little correlation between egg size and developmental time. However, genome size is positively correlated with embryonic developmental time.

JOCKUSCH, E. L. 1997. An evolutionary correlate of genome size change in plethodontid salamanders. Proc. R. Soc. Lond. B 264:597–604.

Living Fossil Identified

While studying postcranial osteological characters of Australian short-necked chelid turtles, Thomson et al. made a remarkable discovery. The Pleistocene fossil species *Emydura lavarackorum* (White and Archer, 1994) from Riversleigh, is indistinguishable from an undescribed extant form of *Elseya* from the Nicholson drainage of Queensland. This is the first time an Australian turtle has been described first as a fossil, representing a taxon presumed extinct, then discovered and redescribed as an extant form.

THOMSON, S., A. WHITE, AND A. GEORGES. 1997. Re-evaluation of *Emydura lavarackorum*: identification of a living fossil. Mem. Queensland Mus. 42(1):327–336.

Monophyly in Iguania and Acrodonta

Macey et al. recently estimated a phylogenetic tree for major lineages of iguanian lizards from 1488 aligned base positions (858 informative) of newly reported mitochondrial DNA sequences representing coding regions for eight tRNAs, ND2, and portions of ND1 and COI. Using their phylogenetic tree, the authors suggest that Iguanidae be redefined to include the eight families established by Frost and Etheridge in 1989. The authors also recommend that Acrodonta, Chamaeleonidae, and Agamidae be restored to their previous content following the suggestions of Schwenk (1994).

MACEY, J. R., ET AL. 1997. Evolutionary shifts in three major structural features of the mitochondrial genome among iguanian lizards. J. Mol. Evol. 44:660–674.

Historical Review

The Stephen H. Long Expedition to the Rocky Mountains was the first expedition to the West that included trained biologists in its party. A recent paper by Dundee discusses the part of this ex-

pedition from Council Bluff to the Rockies and the return to Cape Girardeau. Several of the type localities mentioned, as well as the dates of collection, are corrected and discussed. These include *Elaphe obsoleta, Coluber constrictor flaviventris, Thamnophis proximus, Thamnophis sirtalis parietalis, Sistrurus catenatus tergeminus, Masticophis flagellum testaceus, Cnemidophorus tessellatus, Bufo cognatus, Crotaphytus collaris,* and *Scincella lateralis*. Comments on the amphisbaenid genus *Bipes* and horned lizards, genus *Phrynosoma*, are included.

DUNDEE, H. A. 1996. Some reallocations of type localities of reptiles and amphibians described from the Major Stephen H. Long Expedition to the Rocky Mountains, with comments on some of the statements made in the account written by Edwin James. Tulane Stud. Zool. Bot. 30:75–89.

Russian Journal of Herpetology

The first issue of volume 4 of the *Russian Journal of Herpetology* was published recently. Although still quite young, this journal is attracting authors from around the Northern Hemisphere, and covering a broad range of topics. Anyone seeking more information about contributing or subscribing to this journal can visit their web site at: http://www.folium.ru/rjh.

Now a Cornell Paperback!
Australia is home to some of the most unusual frogs in the world and Michael J. Tyler is acknowledged to be the foremost expert on them. This lavishly illustrated new edition of *Australian Frogs* is the definitive resource on the subject, with updated tables and supplementary text on the fossil record which is vital to historical understanding. Tyler covers the origins, environment, nomenclature, habits, and biology of frogs.

Growth During Middle Age in a Schneider's Dwarf Caiman, *Paleosuchus trigonatus*

WILLIAM E. MAGNUSSON*
ALBERTINA P. LIMA
VALDENISE LOPES DA COSTA
ALDENIZA CARDOSO DE LIMA

**e-mail: bill@cr-am.rnp.br*

Models of growth of reptiles can be difficult to interpret because of large intra-individual variation, and the resulting model of "mean" growth may not represent the most common form of growth of individuals in the population (Rickard et al. 1989). Empirical tests of models may be difficult for long-lived organisms, especially if individuals in some size classes are difficult to capture or recapture. This is the case for *Paleosuchus trigonatus*, for which Magnusson and Lima (1991) produced a growth model based almost entirely on very small individuals and individuals near asymptotic size. They assumed a monomolecular (von Bertalanffy by length) model of growth, but crocodilians frequently have other forms of growth (Magnusson and Sanaiotti 1995; Webb et al. 1983).

Juvenile *P. trigonatus* disperse widely until they are near adult size, at which time they establish permanent territories. Adults are long lived, and the probability of following the growth of intermediate-sized animals is small under normal circumstances. Here we report on an unusual series of events that allowed us to follow the growth of one male *P. trigonatus* and partially evaluate the model of Magnusson and Lima (1991).

When a large male *P. trigonatus* (#4) that occupied the center of our study area disappeared in 1986, the two resident males (#5 and #12) on each side of #4's territory expanded their territories to include the vacant area. The dynamics of the interaction between #4 and #5 have been described partially by Magnusson and Lima (1991). A juvenile male (#37) was captured in the area previously occupied by #4 in March of 1989. In April 1989, #12 was drowned in a turtle trap, and #37 remained in the area. Here, we describe the growth of #37 between 7 March 1989 and 23 July 1996 when he also was drowned in a turtle trap.

We do not know the age of #37 when he first was captured with a snout-vent length (SVL) of 59 cm, but his subsequent growth rate was higher than that predicted by the model of Magnusson and Lima (1991). To estimate his initial age, we applied his observed rate of decline in growth rate with length (-1.022 cm/year/cm), and the maximum asymptotic size of any individual in our study area (90 cm), in the monomolecular model. These values are greater than those in the "mean" model (-1.278 cm/year/cm and 80 cm, respectively) and, if in error, should underestimate initial age. However, the difference between initial age estimated with these parameters and those of the "mean" model is trivial (Fig. 1). Data for one known-age female at 6.9 yr (Fig. 1) indicate that the estimate of initial age of 9.0 yr for the male is reasonable.

Growth of #37 indicates that the underlying pattern of growth for *P. trigonatus* does not deviate grossly from the monomolecular model as do those for *Crocodylus johnstoni* (Webb et al. 1983) and one population of *Caiman crocodilus* (Magnusson and Sanaiotti 1995). The longitudinal data indicate that #37 reached 75 cm SVL at about 15 yr of age, considerably less that the 20 yr predicted by the model of Magnusson and Lima (1991), but still much greater than that expected from growth models of *Caiman crocodilus* (Magnusson and Sanaiotti 1995). As with large species of crocodilians, sexual maturity in *P. trigonatus* is attained at ages between one and two decades.

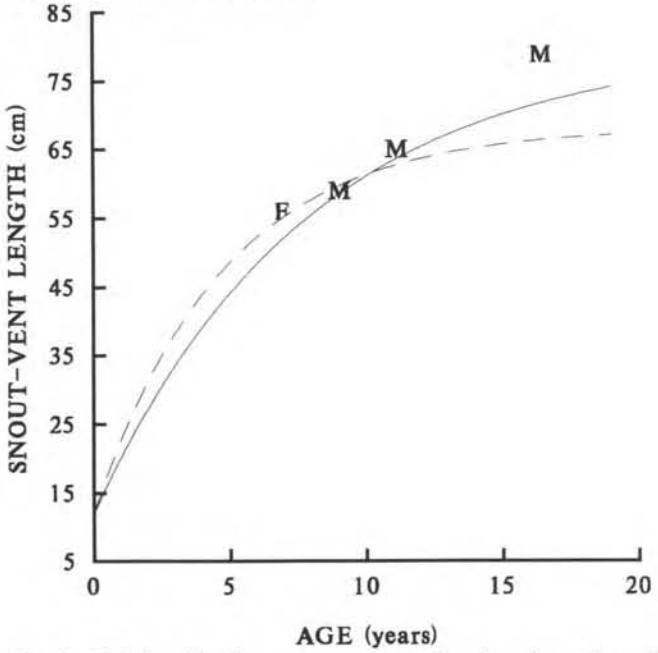

FIG. 1. Relationships between snout–vent length and age for males (solid line) and females (broken line) predicted for a population of *P. trigonatus* by Magnusson and Lima (1991). "F" represents a known age female and "M" represents data for male #37, assuming an age at first capture of 9 years (see text).

Acknowledgments.—We thank Richard Vogt for provoking the events that led to the initiation and termination of this study. The Brazilian Conselho Nacional de Desenvolvimento Científico e Tecnológico provided support in the form of Bolsas de Produtividade (William E. Magnusson), Aperfeiçoamento (Aldeniza Cardoso de Lima), Iniciação Científica (Valdenise L. da Costa), and Apoio Tecnico (Albertina P. Lima).

Behavioral Observations of *Polychrus gutturosus*, a Sister Taxon of Anoles

Polychrus gutturosus (Polychrotidae) is a rarely seen, highly arboreal lizard of lowland rainforests in Central and northern South America. The genus *Polychrus* consists of five species, all characterized by green color, long semiprehensile tails, extremely slow movement, and diets of arthropods and vegetative matter (Greene 1986; Vanzolini 1983; Vitt and Lacher 1981). Because *Polychrus* is the sister taxon of anoles (Frost and Etheridge 1989), this genus is especially important for interpreting evolution among iguanians, yet the behavior and ecology of these cryptic lizards remain poorly known. Here I report locomotor, agonistic, and copulatory behavior in *P. gutturosus* based on field observations in Costa Rica and Panama. I compare this behavior to other species of *Polychrus* and to anoline lizards.

I observed *Polychrus gutturosus* copulating at the La Selva Biological Station, Heredia Prov., Costa Rica on 9 May 1992. The lizards were 2 m up in a tree in tropical wet forest. Observations were made five days after the beginning of heavy rains. I had made no systematic attempts to find lizards of this species, and the observation of copulation was happenstance. My observations of this mating pair were not continuous, nor were individuals marked. However the extreme rarity of this species makes it highly unlikely that more than one male and one female were involved in copulation.

At 0800 h I found a male *P. gutturosus* in a small (~4 m high) *Hemalia patens* (Rubiaceae) tree. At 1200 h I returned and saw the male copulating with a female in the crotch of several small branches of the same tree less than 10 m from the edge of the Puerto Viejo River (Fig. 1). I next observed the pair from 1228–1300 h, from a distance of about 2 m horizontal from the animals. The male was positioned on top of the female with his right hemipenis inserted. The tails were partly entwined and draped over, but not grasping, nearby twigs. The female had an estimated snout–vent length (SVL) of 20 cm and was approximately one third longer than the male. The female was shedding and the only movement was an occasional horizontal head twitch by her. When observed again at 1340 h the pair had not moved, but the male had switched to the other side of the female's tail, using the left hemipenis. The pair separated at 1438 h.

During copulation the female was a dull olive green and the male was brown with faint light bands. Shortly after separation the colors of both animals darkened significantly, the female became a rich green with yellow throat and dewlap, and the male became distinctly banded dark brown and beige. The female then moved away at an extremely slow pace along twigs. The next morning at 0800 h the male was still within 2 m of the copulation site, on a *Heliconia* plant several meters above the ground. The female was not seen again.

H. W. Greene (pers. comm.) observed *Polychrus gutturosus* twice at La Selva. On 20 June 1984 one fell out of a small tree. Later, while being photographed, the lizard moved rapidly up the tree when pursued. On 24 July 1987 Greene caught a female *P. gutturosus* (SVL 170 mm, tail length [TL] 550 mm) in a *Heliocarpus* sp. (Tiliaceae) tree next to the Puerto Viejo river. It had palpable eggs and could switch from brown to green in seconds. When the female was returned to the tree its tail was not curled around a branch, but was kept in contact with branches along the length of the tail. It gaped and extended its dewlap when threatened with a finger. A dead male *P. gutturosus* (SVL 122 mm, TL 430 mm) was found at La Selva lying on a trail on 27 June 1984; the cause of death could not be determined. J. B. Losos collected a subadult *P. gutturosus* (SVL 88 mm, TL 288 mm, MVZ 212068) 40 m above the ground on a leaf next to a canopy tower in Panama. In captivity it locomoted by placing two toes on one side of a branch and three toes on the other side.

Lizards in the genus *Polychrus* are difficult to see because of their immobility, use of twigs as substrate, ability to change color, and long twiglike tail. These characteristics make it hard to distinguish them from their arboreal background (Beebe 1944; Cott 1926; Gorman et al. 1969). *Polychrus gutturosus* is particularly hard to see because it inhabits complex lowland rainforest, unlike *P. acutirostris*, which is found in more open semi-arid habitats (Vitt and Lacher 1981). The limited number of observations suggest that *P. gutturosus* occupies the forest canopy and occurs in low densities. *Polychrus marmoratus* was noted for its association with river courses (Vanzolini 1983), and two of the *P. gutturosus* sightings reported here occurred near rivers. However, river edges represent easy locations to observe canopy animals, perhaps accounting for these observations.

FIG. 1. Copulating *Polychrus gutturosus* in a small tree at the La Selva Biological Station, Costa Rica on 9 May 1992.

Polychrus gutturosus and *P. acutirostris* are sexually dimorphic in color while *P. marmoratus* is not (Vanzolini 1983). *Polychrus marmoratus* can change its color from bright green to somber brown based on changes in emotional or reproductive state (Vanzolini 1983). In aggressive encounters, dominant individuals of *P. acutirostris* became lighter while submissive individuals became darker; color change also occurred during thermoregulation (Vitt and Lacher 1981). *Polychrus peruvianus* and *P. femoralis* both showed ability to change color, although this capacity was less marked in *P. femoralis* (Gorman et al. 1969).

Members of the genus *Polychrus* show similarities to the highly arboreal and tropical *Varanus prasinus* and the Chamaeleonidae (Greene 1986). These lizards are green, have at least partly prehensile tails, and have special modifications of the feet for walking on twigs. All of these taxa have very slow movement, which may prevent detection both by prey and predators (Greene 1986). The only predation event recorded for *Polychrus* was a *P. marmoratus* taken by a white hawk (Beebe 1944), a visual predator.

Anoles frequently copulate in trees and some species have been found to alternate hemipenis use both when copulating with multiple females and when copulating more than once with one female (Tokarz and Kirkpatrick 1991). Like *P. gutturosus*, a male *P. acutirostris* also positioned itself on the back of the female, and pairing lasted 24 h, although most of that time the male did not have a hemipenis inserted in the female (Vitt and Lacher 1981). Copulation in *P. gutturosus* lasted between 2 and 6 hours, while in anoles, mean copulation times were 4.4 min for *Anolis sagrei* (Tokarz and Kirkpatrick 1991) and 10 min for *A. carolinensis* (Crews 1978). J. B. Losos (in litt.) measured copulation time in 11 other species of *Anolis* (14 individuals) and found a maximum copulation time of 17.8 min in *Anolis gundlachi*. Based on observation of copulation in May and palpable eggs in July, *Polychrus gutturosus* appears to breed during the May–December rainy season in Central America. *Polychrus acutirostris* also breeds during the wet season and lays one clutch per year (Vitt 1992).

Green color and arboreality are common and presumably primitive in Polychrotidae, but the special use of toes for locomotion, very long semi-prehensile tail, and long copulation time are unique to *Polychrus* and probably derived for the genus. While copulation has been observed in only two of the five species of *Polychrus*, these two species occupy very different habitats, and in both cases copulation was unusually long compared to anoles. This long copulation time perhaps is related to the general propensity for very slow motion and long periods of immobility in *Polychrus*.

Acknowledgments.—I thank O. Vargas for showing me the pair of copulating *Polychrus gutturosus*, and H. W. Greene and J. B. Losos for sharing their previous observations of this species. H. W. Greene read and commented on an early version of the manuscript. The author was supported by an Organization for Tropical Studies Predoctoral Fellowship sponsored by the Pew Society, and by a Regents Fellowship from the University of California. I thank Deborah and David Clark for facilitating work at the La Selva Biological Station.

Alligator snapping turtles (*Macroclemys temminckii*) are opportunistic scavengers that consume a variety of prey with fish representing a large portion of their diet (Ernst et al. 1994; Pritchard 1989; Sloan et al. 1996). However, little information exists about their preference for specific types of fishes in natural populations. This study investigates the feeding habits of *M. temminckii* as indicated by teleost otoliths in the scats. Considering the endangered and threatened status of these turtles in most states (Ernst et al. 1994; Pritchard 1989), determination of the dietary preferences of *M. temminckii* is important in understanding the ecology and life history of North America's largest freshwater turtle species.

Macroclemys temminckii is considered an ambush predator, luring fish within striking distance by its psuedo-annelid lure, located on the floor of its mouth. In Louisiana, predaceous fish, such as sunfish (*Lepomis* spp.), largemouth bass (*Micropterus salmoides*), and crappie (*Pomoxis* spp.) may be attracted to the lure (Dundee and Rossman 1989). To determine the types of fishes being consumed by *M. temminckii*, teleost otoliths were analyzed from scats. According to Treacy and Crawford (1981), otoliths are often the last remnant of bony fishes to be found in the stomach, intestine, or feces of predators, and often may constitute the only clue to the identity of fishes consumed by marine mammals.

Teleost otoliths have been utilized for determining the feeding habits of a wide variety of piscivorous animals including invertebrates and vertebrates for almost a century (Fitch and Brownell 1968; Schafer 1972; Scott 1903). In a study involving marine mammals, teleost otoliths were found to be reliable indicators of fish consumed (Treacy and Crawford 1981). The numerical proportion of different prey species may be estimated correctly using otoliths from scats according to studies by Dellinger and Trillmich (1988). Although teleost otoliths have been utilized for many years in determining the feeding habits of a wide variety of animals, their use with turtles has been neglected.

Macroclemys temminckii utilized in this study were captured from two northeast Louisiana (USA) water systems in Ouachita Parish, Cheniere Lake and Bayou Desiard. The greatest number of turtles were obtained from Bayou Desiard because of greater sampling effort. Cheniere Lake is located near West Monroe, Louisiana; Bayou Desiard is located in Monroe, Louisiana. Specific collecting sites are described in Harrel et al. (1996). Turtles were captured by hand and with hoop nets between late March 1993, and late September 1993, with most being captured in April, May, and September. Freshwater buffalo (*Ictiobus* spp.) heads and meat were used as bait in hoop nets. Buffalo otoliths were excluded from the otolith analysis in order to avoid bias introduced by the use of bait. The possibility exists that the turtles defecated during capture, but there was no way to control for this. Twenty-four *Macroclemys temminckii* were captured: 2 post-hatchlings, 14 subadults, and 8 adults. Limited holding facilities necessitated placing the turtles in groups. Within one hour of capture, the turtles were transported to galvanized containers 2.5 m diam. Turtles were housed for a minimum of three weeks before release and were not fed during their first week of captivity. However, after one week, freshwater buffalo filets were fed to the turtles. Turtles generally defecated within 36 h of being placed in the tank or after being fed. After defecation, turtles were removed from the containers, and the containers were drained. Fine mesh netting was placed over the drain hole to prevent the loss of otoliths. After the water was drained from the tank, sediments and fecal material were allowed to dry in the bottom of the container. Otoliths were removed from the dried material, cleaned, and stored for study.

Otoliths from the turtle scats were identified by comparison to a reference collection of Recent otoliths maintained by GLS. The vast majority of the otoliths were sagittae, the otoliths found in the sacculus of the labyrinth (Stringer 1979). Sagittae are generally examined in otolith studies because of the characteristic pattern found on the inner face, known as the sulcus, which is the primary means for identification of otoliths (Stringer 1986; Stringer 1992). In some cases, identification of otoliths to species level was not possible because of breakage, etching, or erosion during digestion.

The effect of the digestive acids upon the otoliths is quite variable. In some cases, the otoliths are well preserved compared to otoliths obtained directly from freshly-caught fish. In other cases, the otoliths display various degrees of dissolution and erosion. In rare cases, the otoliths are dissolved to the extent that identifications are severely limited. Another problem encountered was that juvenile otoliths of closely related species, such as the various species of *Lepomis*, are often not identifiable to species level. A potential problem also exists with hybridization of closely related species such as centrarchids (Dawley 1987; Douglas 1974; Trautman 1957).

TABLE 1. Fish species based on otoliths from the scats of *Macroclemys temminckii*.

Sample 1: 5 turtles: adult male (32.7 kg); adult male (20.9 kg); adult female (12.7 kg); female subadult (3.3 kg); male subadult (5.5 kg).

Fish Species identified on otoliths	Number of otoliths (right/left sagitta)
Centrarchus macropterus	4 (2/2)
Lepomis macrochirus	14 (6/8)
Lepomis miniatus	2 (1/1)
Lepomis microlophus	2 (1/1)
Lepomis sp. (juvenile)	1 (1/0)
Lepomis sp. (broken)	2 (2/0)
Micropterus salmoides	3 (3/0)
Pomoxis nigromaculatus	3 (2/1)
Dorosoma cepedianum	21 (12/9)
Centrarchidae (identifiable to family only)	6 (3/3)
Lapillus (unknown)	2
Sagittae (unknown)	3
Otoliths (broken or eroded beyond identification)	13
Total	**76**

Sample 2: 12 turtles: 3 male subadults (less than 4.5 kg each); 9 female subadults (less than 4.5 kg each).

Fish Species identified on otoliths	Number of otoliths (right/left sagitta)
Centrarchus macropterus	1 (1/0)
Lepomis macrochirus	22 (10/12)
Lepomis miniatus	3 (3/0)
Unknown sagittae	2 (1/1)
Total	**28**

Sample 3: 2 turtles: 2 posthatchlings (0.5 kg and 0.9 kg).

Fish Species identified on otoliths	Number of otoliths (right/left sagitta)
Unknown sagittae (broken)	2
Total	**2**

Sample 4: 1 turtle: subadult (7.1 kg).

Fish Species identified on otoliths	Number of otoliths (right/left sagitta)
Lepomis macrochirus	1 (0/1)
Lepomis sp. (eroded)	1 (n/a)
Total	**2**

Sample 5: 3 turtles: adult male (18.1 kg); adult male (16.8 kg); adult female (15.0 kg).

Fish Species identified on otoliths	Number of otoliths (right/left sagitta)
Pomoxis nigromaculatus	4 (2/2)
Lepomis sp. (broken)	1 (1/0)
Dorosoma cepedianum	1 (1/0)
Unknown sagitta (broken)	1 (n/a)
Lapillus (unknown)	1
Total	**8**

Note: Samples 1a, 1b, 2, and 3 from Bayou Desiard; Samples 4 and 5 from Cheniere Lake.

A total of 116 otoliths were recovered from scats of 24 *Macroclemys temminckii* (Table 1). All of the otoliths were sagittae except for three lapilli (from the utriculus of the labyrinth). Of the total otoliths recovered, 81 (69.8%) were identifiable to species level. Of those remaining, 11 otoliths (9.5% of the total) were identifiable to genus or family level. Only 24 otoliths (20.7%) were broken or eroded so that identification was not possible or represented species that were not found in the reference collection. The identification of the otoliths allows for determination of fish species being consumed by natural populations of *M. temminckii*. Also, fish species consumed by the turtles can be compared to species availability in the two water bodies. Fish species recorded as prey of *M. temminckii* and their percentage of the total otoliths are bluegill *Lepomis macrochirus* (31.9%), gizzard shad *Dorosoma cepedianum* (19.0%), black crappie *Pomoxis nigromaculatus* (6.0%), flier *Centrarchus macropterus* (4.3%), red-spotted sunfish *Lepomis miniatus* (4.3%), largemouth bass *Micropterus salmoides* (2.6%), and redear sunfish *Lepomis microlophus* (1.7%). Thus, turtles fed predominantly upon species of sunfishes from the family Centrarchidae (60.3% of the total number of otoliths). The number could be higher considering the unknown lapilli and unidentifiable otoliths.

Our results were compared to species availability data for Bayou Desiard and Cheniere Lake. Studies by the Louisiana Department of Wildlife and Fisheries (rotenone data) indicate that the most abundant species for these two waterways are gizzard shad *Dorosoma cepedianum* and *Lepomis* (the various species of *Lepomis* were classified together). *Lepomis macrochirus* and *Dorosoma cepedianum* were also the most commonly found otoliths in the turtle scats. The large percentage of centrarchids is also in agreement with the species availability data. *Macroclemys temminckii* seems to be feeding on the most available fish species. Contrary to the opinion of many sports fishermen, largemouth bass *Micropterus salmoides* do not seem to constitute a primary prey for *M. temminckii*. Unfortunately, dietary differences between sexes and age was not possible in this study because of the turtles' large size and limited holding facilities.

Many fishes, especially centrarchids, are attracted to littoral areas containing woody debris and logs. *Macroclemys temminckii* in Louisiana have a high preference for forested wetlands and heavily structured microhabitats, such as submerged logs (Harrel et al. 1996; Sloan and Taylor 1987). Turtles may move into structured habitats to better utilize prey resources. However, the recovery of large numbers of *Dorosoma* otoliths in relation to *Lepomis* is somewhat puzzling because these species occupy different habitats (open water versus structured). One possible explanation may be fish kills associated with low dissolved oxygen levels during the summer with *Dorosoma* incurring high mortality. Many of the *Dorosoma* carcasses would drift into the littoral zone where they would be eaten by *M. temminckii*. Although this study demonstrated the use of fish otoliths only in the scats of *M. temminckii* for determining feeding habits, the technique should be applicable for examining the fish composition of other turtles' diets.

Acknowledgments.—We thank the Louisiana Department of Wildlife and Fisheries (District 2, Fish Division) and the Biology Department of Northeast Louisiana University for providing holding accommodations. C. Allen, K. Cascio, S. George, J. Holt, and E. Ritter assisted in the field. Appreciation is due to M. Kontrovitz and S. Harrel for comments on the early drafts of this study. Special thanks are given to N. Douglas, Curator of the Museum of Zoology and professor emeritus at Northeast Louisiana University.

Comments on the Snake Records of *Chilomeniscus cinctus, Crotalus exsul*, and *C. mitchellii* from Islas Magdalena and Santa Margarita, Baja California, México

HUMBERTO WONG
Department of Biology, La Sierra University
Riverside, California 92515-8247, USA
e-mail: humbwong@lasierra.edu

The latest herpetofaunal checklist encompassing the Pacific Islands of Baja California (Grismer 1993) was a comprehensive revision of previous works on this subject (Bostic 1975; Savage 1967; Wilcox 1980; Zweifel 1958). Of these checklists, only the ones of Grismer (1993), Zweifel (1958), and Bostic (1975) include the neighboring Islas Santa Margarita and Magdalena. From these islands, three records originating with Bostic (1975) require clarification as to their current status. These are the records of *Chilomeniscus cinctus, Crotalus exsul* (*sensu* Grismer et al. 1994), and *C. mitchellii*.

The sole museum specimen of *Chilomeniscus cinctus* from Isla Magdalena (USNM 37521) was collected in 1905 by E. W. Nelson and E. A. Goldman and listed by Van Denburgh (1922). Bostic (1975) reported *C. cinctus* only from Isla Santa Margarita whereas Grismer (1993) listed *C. cinctus* for both islands. A search of 23 museums (Appendix I) yielded approximately 735 *Chilomeniscus* specimens, none of which were from Isla Santa Margarita. Nevertheless, *Chilomeniscus* probably occurs on Isla Santa Margarita since suitable, sandy habitat exists in the pass between the northern and southern mountains (Goldman 1951; Nelson 1922). Thus, although the occurrence of *C. cinctus* on Isla Magdalena is reaffirmed, it should not be considered part of the fauna of Isla Santa Margarita until a voucher specimen is obtained.

Crotalus exsul (*sensu* Grismer et al. 1994) was first reported from Isla Santa Margarita by (Klauber 1930:3) on the basis of a single specimen (CAS 56046, Appendix II) collected by J. R. Slevin on 29 July 1922. An additional specimen (SDSNH 6606) was collected on 4 December 1931 by J. R. Pemberton. These records went unreported by Zweifel (1958), Bostic (1975), and Grismer (1993), but were listed by Campbell and Lamar (1989). Furthermore, I observed a dead specimen on the northeastern end of the island on 21 July 1995. Fishermen informed me that they had killed the snake earlier that morning. Bostic (1975) reported *C. exsul* from Isla Magdalena, but a museum search (Appendix I) failed to yield any specimens from this locality.

Numerous authors have reported *C. mitchellii* from Isla Santa Margarita (Campbell and Lamar 1989; Grismer 1993; Klauber,1936; McCrystal and McCoid 1986; Van Denburgh 1905; Van Denburgh 1922; Van Denburgh and Slevin 1914) although Bostic (1975) excluded it from the island's herpetofauna. The oldest museum record I was able to locate from this island (CAS 623) was collected in 1889 by W. E. Bryant. Bostic's (1975) deletion of *C. mitchellii* from Isla Santa Margarita's herpetofauna despite the deposited specimens is juxtaposed by his addition of *C. mitchellii* to Isla Magdalena that lacks voucher specimens. Van Denburgh (1905, 1922), Van Denburgh and Slevin (1914), Zweifel (1958), McCrystal and McCoid (1986), Campbell and Lamar (1989), and Grismer (1993) did not list *C. mitchellii* on Isla Magdalena. Mattison (1996) listed *C. mitchellii* for both Isla Magdalena and Isla Santa Margarita. Because of the conflicting nature of these reports, I provide here clarification on the current status of these records. On 21–22 July 1995, I visited Islas Magdalena and Santa Margarita. I observed a specimen of *C. mitchellii* (Appendix II) on Isla Santa Margarita cratered in the rocky hardpan near the locale where the aforesaid *C. exsul* was killed. On the other hand, no specimens of *C. mitchellii* from Isla Magdalena have been deposited in museum collections (Appendix I). Therefore, based on the lack of voucher specimens from Isla Magdalena, I recommend that only the *C. mitchellii* population from Isla Santa Margarita be recognized.

In summary, the herpetofaunal records for Isla Magdalena should be amended to include *Chilomeniscus cinctus* and exclude *Crotalus exsul* and *C. mitchellii*. Similarly, for Isla Santa Margarita, *C. exsul* and *C. mitchellii* should be recognized as present, whereas *C. cinctus* should be omitted until valid new records are brought forth.

Acknowledgments.—I thank L. Grismer, B. Hollingsworth, H. Kaiser, E. Pakpahan, and N. R. Wong for comments on this manuscript. For field work assistance, I thank E. Gergus, L. Grismer, B. Hollingsworth, C. Mattison, and E. Mellink. Research was funded by the Ryckman Endowment at La Sierra University, Riverside, California. APPENDIX I

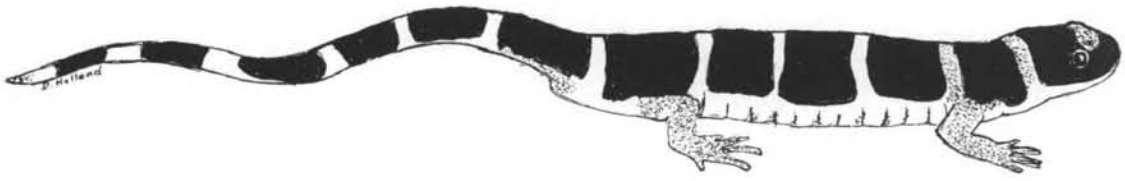
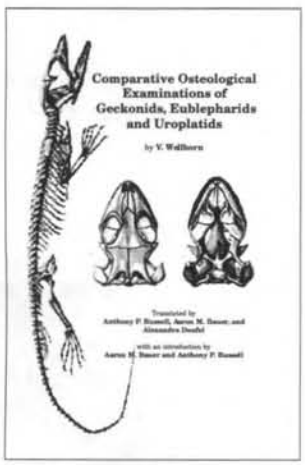
Museum acronyms used follow Leviton et al. (1985) except for the La Sierra University Herpetological Collection (LSUHC) and La Sierra University Photographic Collection (LSUPC). *Chilomeniscus* records were examined from the following museums: AMNH, ASU, BYU, CAS, CM, CSF, FMNH, KU, LACM, LSUHC, LSUMZ, MCZ, MSUM, MVZ, SDSNH, TAIC, TCWC, UAZ , UCM, UF, UMMZ, USNM, UTEP. *Crotalus mitchellii* and *Crotalus exsul* records were examined from the following museums: AMNH, CAS, LACM, LSUHC, MVZ, SDSNH, USNM.



APPENDIX II



Specimens verified by the author or Jens Vindum (CAS).

Chilomeniscus cinctus: MÉXICO: BAJA CALIFORNIA SUR: Isla Magdalena (USNM 37521).

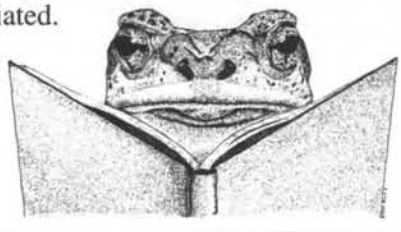
Crotalus exsul: MÉXICO: BAJA CALIFORNIA SUR: Isla Santa Margarita (CAS 56046, SDSNH 6606).

Crotalus mitchellii: MÉXICO: BAJA CALIFORNIA SUR: Isla Santa Margarita (LSUPC S683–S684).

Comparative Osteological Examinations of Geckonids, Eublepharids and Uroplatids

Vera Wellborn

Translated by A.P. Russell, A.M. Bauer and A. Deufel
With an introduction by A.M. Bauer and A.P. Russell.



An important, yet little known paper from 1933 discussing systematic relationships of Gekkonids. The introduction to this translation includes a review of osteological studies since Wellborn's paper appeared as well as a taxonomic cross-reference.

101 pages, 56 illustrations. **$10.00**

Also available:

Mertens 1942 (1997) ***Die Familie Warane***. All three vols. reprinted with new Intro..$68.00

Wanted: Dr. Sergius Kuzmin of the Russian Academy of Sciences needs a copy (or photocopy) of Frost (ed.) 1985 **Amphibian Species of the World: A Taxonomic and Geographical Reference**. Any assistance in helping Dr. Kuzmin obtain a copy of this book would be greatly appreciated.

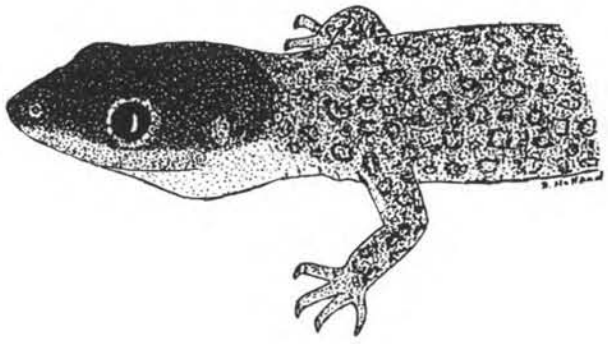
Ingested Molted Skin as Possible Source of Ostracods and Mites in the Gut of Anurans

D. EDUARD VAN DIJK
Department of Zoology, University of Stellenbosch
Stellenbosch 7600, South Africa
e-mail: vdijke@iafrica.com

Mites have been described (Douglas 1992) as tertiary prey of the snake *Psammophylax rhombeatus*, i.e., mites are ingested by earthworms, earthworms are eaten by shrews, and the shrews by the snakes. Reference is made by Douglas to a review of mite-eating in amphibians (Simon and Toft 1992). *Psammophylax* has been reported by FitzSimons (1962) and others to feed on frogs, but the possibility that frogs might be alternatives to shrews was not considered by Douglas.

Considering frogs as a possible source of mites in the gut contents of snakes makes a simpler scenario possible, namely that mites feed on the skin of a frog that is molting, and are ingested when, as is often the case, the frog eats the molt. In connection with this scenario, the following observations on ostracods in the gut contents of *Xenopus laevis* may be suggestive:

Examination of the gut contents of *Xenopus laevis* was part of a Practical in Zoology at the University of Natal. Ostracods were seen in various parts of the alimentary tract, from stomach to rectum, and some observed at all sites, including the rectum, were still alive. It was noticed that the ostracods were associated with frog skin. Two conclusions were drawn. Firstly that the ostracods were ingested with molted skin, and secondly that survival of some of them could have resulted from protection from digestive juices afforded by folds of skin around them. That ostracods avidly attack the skin of tadpoles was observed by the author after capturing tadpoles of *Kassina senegalensis* with a fine net, which also captured and concentrated ostracods, to the obvious distress of the tadpoles when the contents of the net were put in an aquarium.



The scenario offered by Douglas is difficult to check. On the other hand, the finding of mites in association with skin in the gut of frogs would be highly suggestive of the alternate scenario described above. It is offered here in the hope that others might be able to throw some light on the matter from their experience.

There are numerous threats to marine turtle populations, many of which are because of man. There are also natural threats such as predation of eggs and hatchlings. These factors must be studied in an effort to assess their impact on these endangered species. Few studies have been conducted on the effect of insect infestation of marine turtle eggs.

Lopes (1982) identified *Eumacronychia sternalis* (Diptera; Sarcophagidae) living on eggs of the green turtle (*Chelonia mydas*) nesting on the Pacific coast of México. They were reported to have infested nearly 90% of nests transplanted to hatcheries as well as some *in situ* nests. Their data indicated that infestation reduced hatching success by at least 30%.

Other studies have documented larvae of the dipteran family Phoridae, specifically *Megaselia scalaris*, in nests of green (Fowler 1979) and hawksbill (*Eretmochelys imbricata*) turtles (Bjorndal et al. 1985) in Costa Rica. Several studies have shown that larvae of phorids also infest eggs of fresh water turtles (Acuña-Mesen and Hanson 1990; Vogt 1981) and a review of these is given by Iverson and Perry (1994).

In the Mediterranean, only coleopteran larvae have been reported infesting eggs of the loggerhead turtle (*Caretta caretta*) in Turkey (Baran and Türkozan 1996). No other published data exist on insect larval infestation of marine turtle nests in the Mediterranean. Our study was carried out in 1994 and 1995 on the north coast of the island of Cyprus (eastern Mediterranean), where both *Chelonia mydas* and *Caretta caretta* nest (Broderick and Godley 1996). Work was carried out at the main nesting site at Alagadi and other beaches along the coast. After hatching had occurred, nests were excavated to examine the clutch remains and determine the hatching success of individual nests. In the event of insect larvae being discovered among the remains, the number of infested eggs was recorded and the larvae taken to the laboratory to rear. Occasionally, we found pupae while collecting sand samples from the wall of the nest for other analyses. Samples were kept in glass jars covered with muslin at room temperature and checked at two-day intervals. When adult insects were observed they were left for at least 24 h to allow cuticles to harden before they were removed and preserved in alcohol. Samples were then returned to the U.K. for identification. In some instances other invertebrates were recorded in the nest and either identified immediately or preserved for later study.

In 1995, 11 of the hatched *C. caretta* nests at Alagadi were infested with insect larvae. This represents 23% of hatched nests that were excavated. In nests of *C. mydas*, insect larvae were recorded in 5 (9%) nests. In these clutches, infestation had occurred in 4.6% (N = 5, SE = 1.45) of *C. mydas* eggs and 10.6% (N = 11, SE = 4.81) of *C. caretta* eggs. Infested nests also were found at other beaches, although their effects were not quantified.

In Cyprus, *C. mydas* lay their eggs at a greater depth than *C. caretta* (Broderick and Godley 1993). This may account for the lower rate of infestation of *C. mydas* nests, their greater depth making them less accessible to burrowing female insects or their larvae. An additional factor may be that *C. mydas* covers her eggs with a large mound of sand, possibly masking their smell. Although levels of infestation are given for those nests that were hatched and excavated, we do not know to what extent unhatched nests may have been infested. In addition, infestation may have occurred in hatched nests at an earlier date and larvae migrated away from the nest to pupate in the sand. Nests can be marked accurately at laying and in principle be excavated at any time to search for insect infestation. However, this intrusive method may not be compatible with proper conservation practice.

Adult insects were reared successfully from seven nests. These samples have been identified as containing four species of flies from two different families (Diptera: Sarcophagidae and Phoridae) and one species of wasp, *Brachymeria podagarica* (Hymenoptera: Chalicidae). The sarcophagids are *Sarcophaga (Parasarcophaga) crassipalpis, Sarcotachina subcylindrica* and a species of *Wohlfahrtia*, possibly *indigens*. The phorid was the well-known polyphagous species *Megaselia scalaris*, which is worldwide in its distribution.

Sarcophaga (P.) crassipalpis and *S. subcylindrica* were found in the nests of both species of turtles. *Megaselia scalaris* was reared from a *C. caretta* and the *Wohlfahrtia* sp. from a *C. mydas* nest. The wasp is known to be a widespread parasitoid of muscoid flies, including the Sarcophagidae (Beaver 1986) and, in this instance, was found in association with *S. (P.) crassipalpis* in a *C. mydas* nest.

During earlier work in 1994, two other sarcophagids were recorded, both of which were reared from *C. caretta* nests. These were a species of *Sarcophaga (Parasarcophaga),* either *argyrocephala* or *hirtipes*, and an as yet unidentified member of the tribe Amobiini, subfamily Miltogramminae. Other observations include one larva of a beetle (Coleoptera: Scarabaeidae), not identifiable to species level, found in a *C. mydas* nest. In addition, one of the nests with fly larvae also contained an antlion larva (Neuroptera: Myrmeleonidae), and in several other nests enchytraeid worms (Annelida) were recorded in eggs of *C. caretta.*

There are several stages at which turtle nests could be attacked by insects. At the time of laying, eggs are exposed and cloacal secretions may act as an attractant. Infrequently, flies have been observed (by ACB) landing on eggs at this time. However, compared to the incubation period for the turtle eggs in Cyprus of 42–60 days (Broderick and Godley 1996), the life cycle of these insects is brief, particularly in the prevailing high temperatures found in Cyprus. *Megaselia scalaris*, for example, may complete this process in 20–25 days (Disney 1994) and *Sarcophaga* in as little as 13 days (Busvine 1980).

Members of the family Sarcophagidae, known colloquially in English as flesh-flies, are strongly attracted to both freshly dead and decomposing animal tissue. They are viviparous, the female producing active first instar larvae. The flies probably deposit their larvae on the sand and the larvae then burrow to the food source. This has been observed and experimentally demonstrated with another species that is predatory on earthworms (Lopes 1982). Several members of the Phoridae are able to burrow as adults through the soil, up to a depth of one meter, in order to lay their eggs on buried corpses (Disney 1994). We believe that turtle nests are exposed to potential infestation by insects at any time during the development of the embryo, despite being buried immediately after laying.

Lopes (1982) indicates that insect infestation is much higher in transplanted *C. mydas* nests. This may be because of exposure or damage to some of the eggs during this process, concentrating the nests in a small area, or a combination of these factors. To reduce the latter problem, a number of separate hatchery sites, relocated each season, might be considered as a preventative measure. Our observations of the parasitoid wasp *Brachymeria podagarica* indicate that, in Cyprus at least, it may exert some natural biological control over the sarcophagid fly infestations. Whether this insect could or should be encouraged in artificial hatcheries is debatable, but may be worth investigation.

These infestations may be primary factors in the reduction of the success of a nest or only affect moribund eggs or embryos. Their attraction to the nest in the first instance is likely the result of decay; whether they will subsequently attack viable eggs after utilizing their initial food source is not known. In a study on *Graptemys pseudogeographica*, a species of freshwater turtle, Vogt (1981) recorded infestation in eggs containing live hatchlings and suggested that most infestation occurred at pipping. Although it seems possible that infestation of nests poses a direct threat to incubating clutches, these insects may, in effect, remove decaying material from the nest, thereby decreasing the risk of further infection.

Acknowledgments.—This work was funded by a University of Glasgow postgraduate scholarship with field assistance from members of Glasgow University Turtle Conservation Expedition. Many thanks goes to all those that identified samples: Nigel Wyatt (Natural History Museum, London), Henry Disney (University of Cambridge), Roy Crowson (University of Glasgow), Peter Skidmore, and Richard Askew. Thanks also to Roger Downie and Brendan Godley for constructive comments on the manuscript.

Electronic Measurement of Saltatory Locomotion

PETER A. ZANI*
Department of Zoology and Oklahoma Museum of Natural History
University of Oklahoma, Norman, Oklahoma 73019, USA

**Present address: Department of Biology, University of Oregon*
Eugene, Oregon 97403-1210, USA
e-mail: pzani@darkwing.uoregon.edu

Locomotor performance of ectotherms has become a very popular issue in recent years (for review see Garland and Losos 1994) and the most common measure is sprint speed (e.g., Huey 1982; Losos 1990; Bauwens et al. 1995; but see Zani 1996). Jumping ability, like sprinting, is an ecologically relevant measure, and may offer insight into an animal's fitness (see Arnold 1983; Tsuji et al. 1989). Recently, electronic timing systems have been used to measure accurately locomotor performance (see Huey and Hertz 1982; Losos 1990). In this paper I present an extension of the current uses of electronic timing systems to measure performance of saltatory locomotion. The techniques presented here can be used to measure jump angle at takeoff, speed of a single jump, and locomotion speed in a series of consecutive jumps.

The construction of electronic timing systems necessary to implement these techniques, including the necessary programming, has been described elsewhere (Huey et al. 1981; Miles and Smith 1987) and will not be discussed extensively here. In essence, such systems consist of a series of infra-red light emitters and detectors. In normal operation (data gathering mode), each emitter is aligned to illuminate a detector. This causes the logic input to the data gathering computer to be a logic zero (0) for that channel. When an object passes between the emitter and the detector this logic level changes to a one (1). When this transition occurs it is called an event. The first event causes the computer to make a copy of its internal, free-running clock, mark that channel as "read," and then look at the next channel. Each time a photocell light beam is tripped, the free-running clock is read, and that channel is marked. When the number of events (input into the computer a priori) and the number of channels tripped are the same the computer returns to the monitor mode. All channel and time data received from the event computer are converted from binary mode by the data gathering computer to a floating point number for display and storage. The elapsed time between events is obtained from the data gathering computer. Speed is simply the distance separating the photocells divided by the elapsed time it takes an animal to travel that distance.

For measurement of sprint speed, photocells are placed at a known distance from the start point along the wall of a narrow racetrack (often at 0.25 m intervals). To measure jumping ability I positioned 20 photocells in a vertical array (Fig. 1) consisting of two pieces of Plexiglas (36 cm x 12 cm x 0.5 cm) affixed to a base (12 cm x 12 cm x 0.5 cm); holes were drilled at approximately 2 cm intervals, but one could vary this distance to suit the size of the animal being tested. The photocells are partitioned into two columns 8 cm apart. The first column is comprised of four photocells while the second column contains the remaining 16 photocells. The emitters are placed in one wall and the detectors placed in the opposite wall. When an animal is induced to jump through the photocell "plane" it breaks the infra-red light beams in the first group to initialize timing and breaks the beams in the second group to end timing. The time interval recorded between photocells is the time it takes to travel the 8 cm between the photocell columns. Because it is possible to record which individual detector is tripped (Miles and Smith 1987) one can determine the height of that detector. By recording the distance of the animal from that detector prior to the jump, it is relatively simple to determine the initial angle of each jump by measuring the two remaining sides of the right triangle it forms with starting position and the photocell-column base (Fig. 1). Jump angle can be measured even if more than one detector is tripped during a jump by using either the height of the detector first tripped or the average detector height tripped. By marking an animal's start and finish points, single jump length also can be determined.

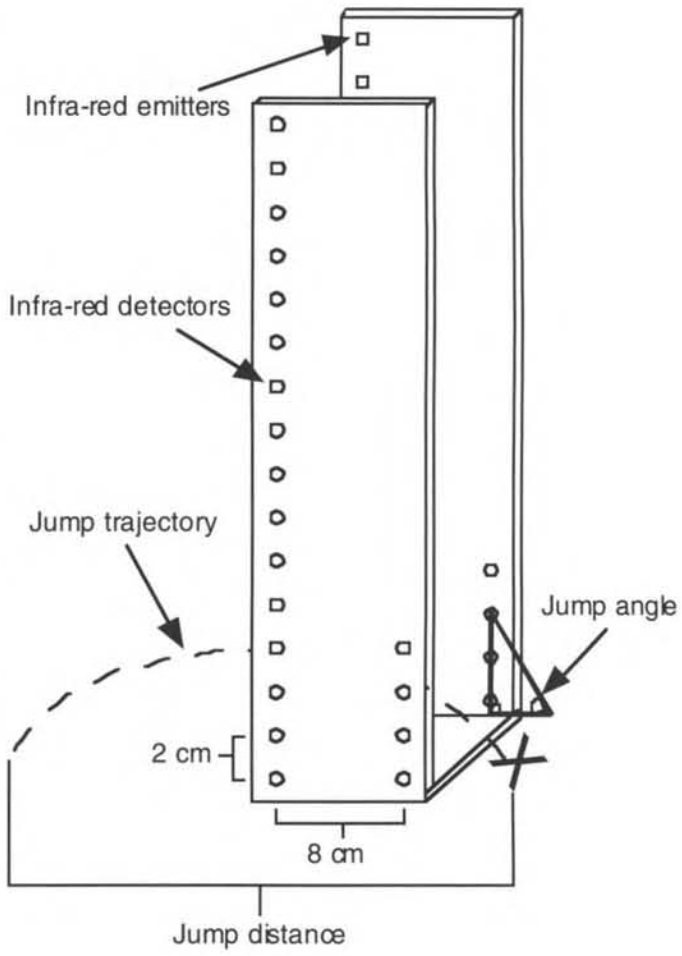

FIG. 1. Vertical photocell array designed to measure jumping ability. Infra-red photocells attached to the data gathering computer (not shown) measure elapsed jump time. "X" denotes the animal's start position. Jump angle is determined by measuring the three sides of the right triangle depicted (see text). Note: it is possible to add more than four photocells to the first column of photocells.

In addition to measuring components of single jumps, locomotion speed of saltatory animals over a longer distance also may be measured with the electronic timing system. To accomplish this one places the first group of four photocells at the beginning of a narrow racetrack and the second group of 16 photocells in a separate vertical array at the end of the racetrack. One can then estimate locomotion speed over a series of consecutive jumps.

Electronic timing systems can be used effectively to collect data estimating the components of jumping and sprinting in frogs, lizards, insects, and mammals. This technique should facilitate studies of saltation, a locomotion type yet to receive much attention.

Acknowledgments.—I thank R. Whitehead for building the vertical photocell array, J. B. Losos and D. B. Miles for helpful comments about electronic timing systems, and R. A. Schmaeng for building the timing system used to test these ideas. Development of this technique was made possible by a grant from the National Science Foundation (DEB-9200779) to L. J. Vitt and J. P. Caldwell.

Monitoring the terrestrial movement of amphibians has traditionally been done using drift fences and pitfall traps (Corn 1994; Dodd and Scott 1994). Amphibians moving on the ground intercept the drift fence and are redirected towards traps at either end of the fencing. A number of problems have been recognized that influence the suitability of the pitfall in some circumstances. Because organisms with good climbing abilities (e.g., *Notophthalmus* spp., *Hyla* spp.) and jumping abilities (many *Rana* spp.) may escape, the trapping success of pitfalls is reduced when targeting these species (Corn 1994; Dodd and Scott 1994). Pitfalls are also difficult or impossible to set in certain locations because of rocky and root-bound substrates, frozen ground, or seasonally flooded areas. To overcome these difficulties, a simple and effective low cost trap was developed. We named it the side-flap pail-trap. The design, application, and success of the traps are outlined below.

Construction of the trap.—The main body of the trap consists of a plastic 11.4 L pail with a lid. Used commercial ice cream containers work well and are very economical. A 6 x 6 cm entrance opening is cut into the side of the pail 9 cm from the bottom. Two 1 cm slits are made 5 cm apart and 1 cm above the opening. An 8 cm square piece of stiff 1/4" x 1/4" galvanized steel mesh is hung on the inside of the pail using garbage twist ties inserted through the slits and the mesh. The mesh flap is cut larger than the opening and shaped to the curve of the pail so there are no gaps to allow escape. The door acts as a one-way valve; it swings into the pail and falls back flat against the bucket after an animal passes through. On the side of the pail opposite to the door, a 12.5 x 15 cm window is placed 7.5 cm off the bottom. This opening is covered on the inside by 1/4" x 1/4" galvanized steel mesh and attached on all four sides with duct tape (Fig. 1).

Set up in the field.—Each trap was buried 9 cm into the ground so the bottom of the entrance door was flush with ground level. A funnel made of the same 1/4" x 1/4" mesh was placed in front of the door to direct the organisms from the drift fence into the trap opening. To make the funnels secure, they were pushed approximately 3 cm into the ground and were stapled to the wooden stake at the end of the drift fence. Mud, grass, twigs, or rocks were used to cover any gaps between the funnel and the surface of the pail. Fences were 50–75 cm high x 30–40 m long nylon fabric stapled to wooden stakes. The bottom edge of the fence was buried in the ground. Four traps per fence were used with two traps on each end of the fence. Water and a 600 g rock were placed in each trap to provide refuge for the animals and to stabilize the trap.

The side-flap pail-trap required minimal set up time; each trap took approximately 0.5 person hours to set up and cost roughly

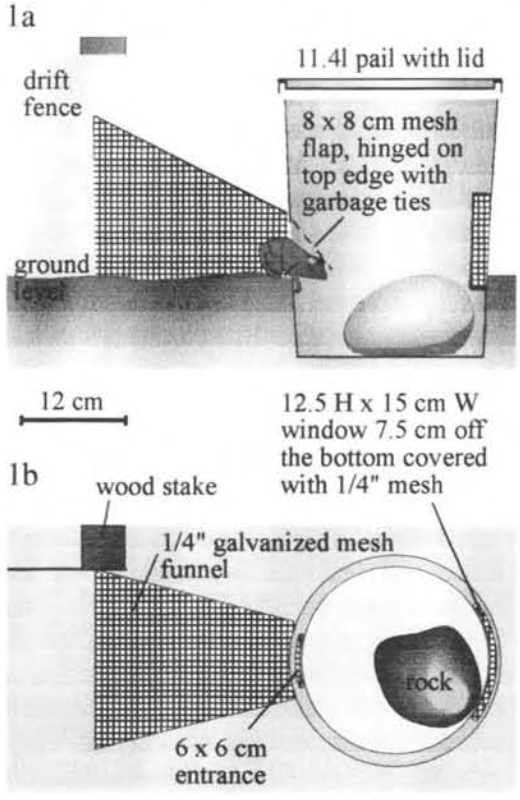

FIG. 1. Diagram showing a cross-sectional side view (1a) and top view with the lid removed (1b) side-flap pail-trap.

$1.00 (US). Garden shovels and spoons were the extent of additional equipment required. Traps were set up in field, forest, and riparian habitats. Substrate and flooding problems associated with pitfall traps were not a problem. The traps are durable, requiring minimum maintenance throughout the field season (we replaced duct tape on windows as required), and were removed easily at the end of the season by simply pulling them from the ground.

Monitoring of the traps.—The traps were used in a mark-recapture study to monitor amphibian movements into and out of 12 ponds in two different landscapes in the Annapolis Valley, Nova Scotia. The traps were used in habitats ranging from dry fields, forests, and riparian areas including stream flood plains. Traps were checked over a total of 195 days; everyday during rainy periods and every second day during drier, sunny periods. We checked the traps by pulling off lids and animals were retrieved easily because the bottom of the trap was close to ground level. Lids on the traps provided shade for animals and protection from predators.

Success of the traps.—Although this study was not designed to test the differences in capture success between the pitfall trap and the side-flap pail-trap, our new trapping technique was highly effective for capturing *Rana sylvatica, R. pipiens,* and *R. clamitans*, all considered to be good jumpers. Although abundances and species trapped were pond and landscape dependent, the following numbers have been included to show the relative success of the traps over 195 days: 196 *R. sylvatica*, 828 *R. pipiens,* and 324 *R. clamitans*. Juveniles of these species often were caught en masse and numbers of up to 30 individuals per trap were not uncommon. Other amphibian species trapped included *Ambystoma maculatum* (239), terrestrial phase of *Notophthalmus viridescens* (324), *Bufo americanus* (74), *Rana catesbeiana* (2), and *Hyla crucifer* (30). Small mammals (63) also were trapped; their survival rates approximated 30%, better than the standard pitfall trap with 0% survival (Bury and Corn 1987). Other occasional captures included three *Chrysemys picta* and six *Thamnophis sirtalis*.

In summary, the side-flap pail-trap, when used in conjunction with funnels and drift fencing, is a very effective technique for capturing amphibians in terrestrial habitats, especially ranid frogs. Setting the traps at ground level minimizes installation and dismantling times, and problems with substrates are avoided. Although the efficacy of the traps compared to other trapping techniques has not been assessed, our experience suggests that the side-flap pail-trap is a reliable technique for monitoring amphibian movements in terrestrial environments.

Acknowledgments.—We thank P. Taylor and S. Montonen for improving this manuscript. Thanks to S. Mockford for his suggestions on improving the trap design. We acknowledge ACWERN for providing research funds to carry out this study.

Implanting an Arterial Catheter in Softshell Turtles

BRIAN P. BAGATTO*
EMMETT L. BLANKENSHIP
and
RAYMOND P. HENRY
Department of Zoology and Wildlife Science, 101 Cary Hall
Auburn University, Auburn, Alabama 36849-5414, USA

**Present address:*

When numerous blood samples are required from the same experimental animal, the preferred method of drawing blood is via an implanted catheter. Catheterization is especially advantageous in experiments involving the measurement of labile physiological parameters, such as blood acid-base balance, because it minimizes disturbance and promotes uniformity of sampling. Kerr and Frankel (1972) have discussed the inadequacies of the cardiac puncture technique in turtles when measuring blood gases. Additionally, turtles are able to displace their heart by retracting their head, therefore, the reliability of the sampling location is uncertain. Repeated cardiac sampling may not only damage the heart, it may also adversely affect physiological parameters because of prolonged handling of the animal. It is for similar reasons (in this case, vessel damage and prolonged handling) that repeated sampling of venous blood from extremities is not favorable. Implanting a catheter in, or cannulating the subclavian artery in *Trachemys scripta* has been briefly described (Jackson et al. 1974) and has proven to be a reliable method for repeated blood sampling. Ultsch et al. (1984) have mentioned a similar procedure for softshell turtles (*Apalone spinifera*), but provided insufficient detail to repeat this procedure. Here, we describe this procedure in more detail, including potential problems, to guide researchers who wish to apply this technique.

Recently it has been considered unacceptable to anesthetize reptiles using ice. This not only creates unnecessary stress to the animal, but it does not provide a satisfactory level of anesthesia. In softshell turtles, 3-aminobenzoic acid ethyl ester (MS-222, Sigma) provided an appropriately timed (about 1 h) and reliable anesthesia for this surgical technique. *Apalone ferox* (N = 17; mean mass ± SE = 1602 ± 343 g; range = 400–5900 g) and *Apalone spinifera* (N = 10; mean mass ± SE = 1944 ± 446 g; range = 312–4200 g) were anesthetized with MS-222 and cannulated using the following procedure. Anesthesia and surgery were performed at room temperature, which ranged from 22°C to 25°C. Using a dosage of 500 mg/kg, an unbuffered MS-222 solution (100 mg/ml) was injected intracoelomically (Bagatto et al. 1997). After injection, turtles were placed in an aerated, buffered solution of MS-222 (1 g/L with 15 ml of 0.5 M Na_2HPO_4 per L). Induction times ranged from 10 to 75 minutes (Bagatto et al. 1997). Animals were deemed anesthetized when manual pedal stimulation produced no withdrawal reflex.

The incision area was prepared in a routine manner for aseptic surgery using Betadine® as the antiseptic. A semicircular incision with its convexity directed anterolaterally was made on the left anterior quadrant of the plastral area. This created a "half-moon" flap with a base 2.5–3.0 cm long adjacent to the bony portion of the plastron and midway between the base of the neck and the left forelimb. Care was taken to avoid the numerous surface vessels, however, clotting occured quickly if they were transected. Blunt

dissection through the deltoideus muscle layer was directed toward the heart. A microdissecting retractor was used to hold the incision open and facilitate searching for the subclavian artery. The subclavian artery is the most anterior of a group of arteries that leave the heart and cross the ventral surface of the trachea and, therefore, is the first major artery encountered during dissection. Once the artery was isolated, it was exteriorized and ligated distally. Using cross action forceps with aquarium tubing mounted on the tips to reduce trauma, the artery was clamped proximally leaving enough length for arterial incision and insertion of the cannula (about 1.5–2.0 cm). An incision was made in the artery and PE 90 polyethylene tubing filled with heparinized reptile ringers was inserted approximately 1 cm into the artery toward the heart (Fig. 1). The insertion end of the cannula had been cut to a moderate bevel and the tip had been dulled to prevent piercing of the artery. Perforation of the cannula near the tip with a fine gauge needle may aid in preventing occlusion. The cannula was secured in two places within the artery using fine silk suture ligatures (Fig. 2). The arterial clamp was then removed and the cannula was flushed with heparinized reptile ringers.

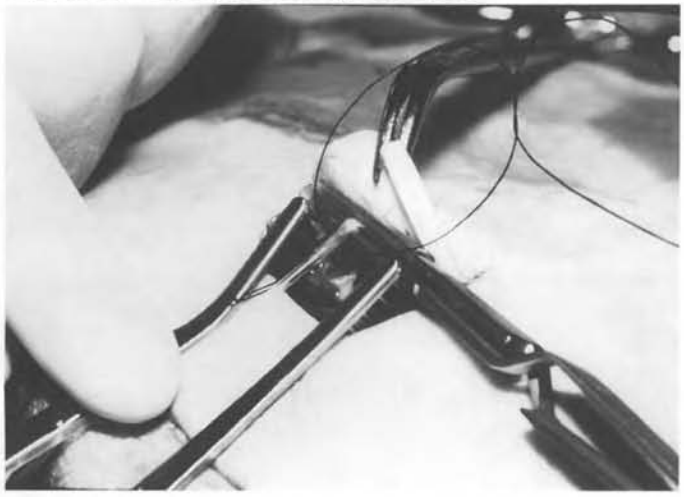

FIG. 1. Insertion of the polyethylene cannula in the left subclavian artery of a Florida softshell turtle, *Apalone ferox*.

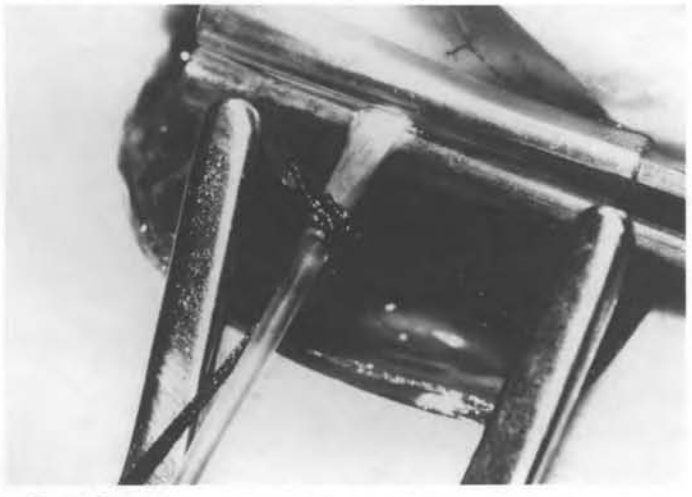

FIG. 2. Cannula secured with two fine silk suture ligatures.

The extremely long neck of softshell turtles allows them to displace their heart and attached vessels via neck movement; therefore, the cannula was positioned carefully within the turtle. After the cannula and artery were placed back into the animal, care was taken to ensure that the cannula was loose enough to accommodate normal movement but would not be occluded by the vessel wall. We recommend aspirating and flushing the cannula while flexing and extending the turtle's neck. If blood can be withdrawn during the full range of neck motion, the cannula and artery are in optimal position. The incision was sutured and sealed with tissue glue (any cyanoacrylate ester compound will do), which also secured the cannula at the incision. The cannula also was sutured to the plastron 2 cm from the incision and on the midventral left side so that it could be routed to the dorsal surface, thus avoiding the limbs (Fig. 3).

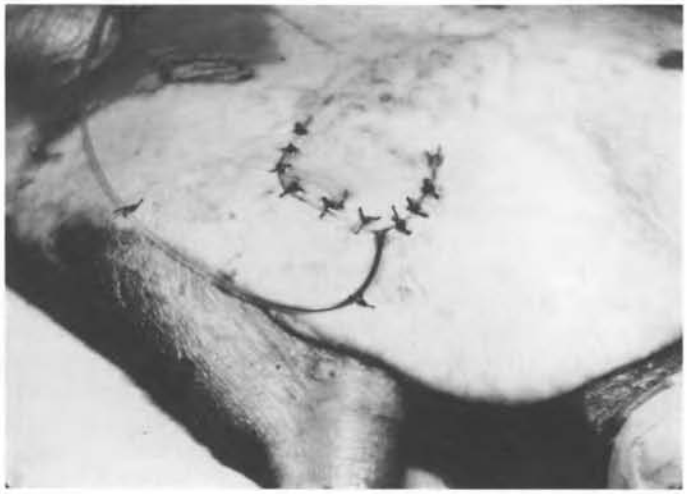

FIG. 3. Completed surgery showing sutured flap with cannula sutured in position.

The turtle should be recovered under running water, with care being given to ensure adequate ventilation. When the turtle can hold its head up under its own control, it should then be transferred to a disinfected opaque container filled with enough water to completely cover the shell. A perforated lid will secure the container and allow the animal to recover in darkness. Full recovery may take as few as 12 h, but at least 18 h of recovery time should be given. Blood sampled should be replaced with an equal volume of heparinized reptile ringers and sample volumes may range from a few microliters to 25% of the total blood volume of the animal (Bagatto and Henry, ms. submitted). This type of occluding arterial cannula should be used preferably in short term experiments. Experiments requiring a cannula to be operational for more than four days should utilize a nonoccluding procedure or a peripheral vessel. Experiments involving arterial catheters are usually terminal; thus, the catheters are not normally removed.

This simple yet effective way for anesthetizing and cannulating softshell turtles (*Apalone spinifera* and *A. ferox*) of variable size (300–6000 g) can be utilized so that arterial blood may be drawn repeatedly with minimal disturbance to the animal.

Acknowledgments.—We would like to thank Paul Buttenhoff for the photographs. This work was supported by NSF IBN 83-04844 to RPH and by an Auburn University Graduate Research Award to BPB.

An Observation Technique for Snake and Lizard Hemipenes with Comments on Preparation

RUBENS NOBUO YUKI
Departamento de Zoologia, Museu Paraense Emílio Goeldi
Caixa Postal 399, Belém, Pará, Brazil. Cep: 66040-170
e-mail: yuki@Goeldi.museu-goeldi.br

The hemipenis preparation technique of Pesantes (1994) has permitted observation of the hemipenis of preserved snakes (e.g., species of *Xenoxybelis* and *Oxybelis* [Machado 1993], and *Helicops danieli* [Yuki 1994]). I have adapted Pesantes' technique (treatment in 2% KOH and 0.1N HCl solution, with subsequent filling of the organ with agar-agar) to prepare lizard hemipenes with good results (e.g., *Teius oculatus*, *Ameiva ameiva*, *Polycrus marmoratus*, and *Neusticurus bicarinatus*).

Unfortunately, a semi-everted hemipenis, prepared with Pesantes' technique, will not produce a general shape similar to that of organs that are completely everted, as the action of the KOH solution is not uniform. In order to allow later preparation of hemipenes of preserved snakes, it is preferable to not evert the hemipenes during preservation or else adapt the procedures of Manzani and Abe (1988) for hemipenial eversion. For lizards, it is preferable that the hemipenes remain inverted because complete eversion often will not occur satisfactorily from strong pressure caused by injecting formalin into the tail of some species (e.g., *P. marmoratus*, *N. bicarinatus*), in contrast to what occurs in other species (e.g., *A. ameiva*).

The observation of prepared hemipenes also may be difficult because of low refraction of light. I have used Book and Shear's (1974) muscle coloring solution to successfully color lizard and snake hemipenes. The composition of the solution is 1 g iodine + 2 g potassium iodine + 100 g distilled water. The potassium iodine should be dissolved in the water first, after which the iodine will more easily go into solution. The procedure to color the organs is simple: (1) immerse the hemipenis in the prepared solution for 5–10 seconds, (2) wash the hemipenis in water and observe, and (3) immerse the hemipenis in 70% ethanol for an indeterminate time until the organ reaches the desired tonality. This technique favors observation because it permits coloration of organs in various degrees of intensity, depending upon one's needs. Another benefit of this technique is that after the solution is applied, it returns the organ to its original color, even after lengthy immersion in alcohol.

Acknowledgements.—I thank Ulisses Galatti for comments on the manuscript. Financial support was provided by the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Brazilian Federal Government.

Restraining and Marking Method for Snapping Turtles, *Chelydra serpentina*

HUGH QUINN
and
TIM PAPPAS
Cleveland Metroparks Zoo, 3900 Brookside Park Drive
Cleveland, Ohio 44109, USA
e-mail: hquinn@ix.netcom.com

Because of the size and aggressive nature of common snapping turtles (*Chelydra serpentina*), marking them by unique shell notching can be dangerous and difficult. We describe a safe and quick way to accomplish this task.

A turtle is placed on the ground and a polyvinyl chloride (PVC) pipe of appropriate length and diameter is placed over the turtle's head and held in place with one hand by the investigator. When positioning the pipe, caution should be taken to assure the hand grasping the pipe is out of turtle striking range. The front of the investigator's foot is then firmly placed on the posterior margin of the turtle's carapace (Fig. 1). The turtle becomes calm in a few seconds and remains so for several minutes. In this posture, the investigator can file notches in the carapace with the free hand for individual turtle identification (Ferner 1979).

We have found that a 10.16 cm diam pipe, ca. 60 cm in length, allows us to safely restrain common snapping turtles 4.54 kg and larger. Smaller pipe diameters are available, and work well with smaller turtles.

FIG. 1. A 15.3 kg common snapping turtle (*Chelydra serpentina*) with a 39.2 cm carapace is safely restrained and marked.

To expedite the marking process, we use a rotary power tool (Fig. 1). A circular grinding bit affixed to the power tool is appropriately shaped with a grindstone so it will carve the desired notch shape when touched to the shell. Shaping the bit is accomplished while both the bit and grindstone are rotating. Both electrical and

battery powered rotary power tools are available. Electrical tools obtain greater revolutions per minute (rpm) than battery operated units, expediting the notching process, but battery operated units are particularly useful in the field, where electrical power is not available. Several rechargeable battery packs can be utilized when marking a large number of turtles. Units reaching speeds of 10,000 rpm or greater are needed to rapidly notch the shell. Care must be taken not to cut soft tissue, potentially injuring the turtle.

HERPETOLOGICAL HUSBANDRY

A Safer Capture Technique for Large Reptiles

C. J. FRANKLIN
and
R. W. HARTDEGEN
Department of Herpetology, Dallas Zoo
650 South R. L. Thornton Freeway, Dallas, Texas 75203, USA

Many techniques have been suggested for the safe handling of large and potentially dangerous reptiles. The use of a snare placed around the neck of lizards and crocodilians has been described (Fowler 1978; Jones and Hayes-Odum 1994). Another method requires the specimen's head to be pinned down or covered with a cloth prior to grasping it behind the head with one hand, while simultaneously securing the animal at the base of the tail (Ball 1972). However, information regarding the actual approaches to securing these animals is limited. Because of the potential harm that large reptiles can inflict through bites, scratches, and tail slaps, additional procedures that facilitate restraint should be considered.

Staff members at the Dallas Zoo's Department of Herpetology have employed a simple method that involves spraying the animal in the face with a fine mist of water. The spray generally results in the animal turning its head in the opposite direction and/or closing its eyes. Often the water alone obstructs the animal's vision sufficiently to permit a safer approach. This technique has been used effectively on large lizards such as *Varanus giganteus, V. gouldii*, subadult *V. komodoensis, V. olivaceus*, and *Iguana iguana*. Further, this technique has been used successfully for crocodilians (*Crocodylus acutus*, *Alligator mississippiensis*; R. Reams, pers. comm.), and large pythons (*Python* spp.; A. Mitchell, pers. comm.). Application of this technique could reduce the risk of injury to handlers of large reptiles.

THE ASSOCIATION OF REPTILIAN AND AMPHIBIAN VETERINARIANS

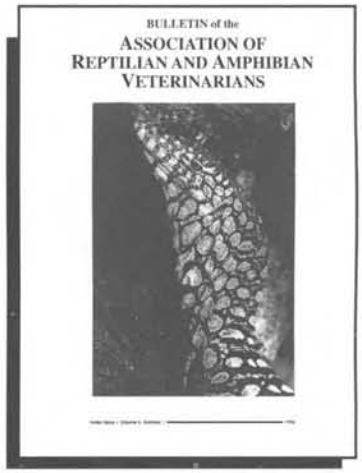
The Association of Reptilian and Amphibian Veterinarians (ARAV) *is a nonprofit international organization of veterinarians and herpetologists founded in 1991. Our goal is to improve reptilian and amphibian veterinary care and husbandry through education, exchange of ideas and research.*

Membership is open to all interested parties, benefits include:

Quarterly Bulletin

Peer reviewed, referenced, indexed and a concise information source for state-of-the-art herpetological veterinary medicine.

Membership Directory



List of members.

Annual Conference

Members receive discount on tuition.

The Annual Conference and published Proceedings includes a wide variety of pertinent topics; nutrition, husbandry, infectious diseases, basic and advanced diagnostics, surgical and medical therapeutics, wetlabs and workshops designed to keep you current in an everchanging field.

The ARAV needs your participation. We invite you to join forces with more than 1,300 other professionals. Fill out the membership application and support the organization that is improving veterinary care of reptiles and amphibians.

The Bulletin of the ARAV includes these sections:

- In My Experience
- Case Reports
- Care-in-Captivity
- Original Articles
- Techniques
- Pathology Pages
- Nutrition Notes
- Literature & Book Reviews
- Announcements

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 28, Number 1 (March 1997).

CAUDATA

PLETHODON MISSISSIPPI (Mississippi Slimy Salamander). **VOCALIZATION.** Sound production is limited in the order Caudata (Duellman and Trueb 1994. Biology of Amphibians. John Hopkins Univ. Press. Baltimore, Maryland. 670 pp.). However, vocalization has been documented in the family Plethodontidae (Maslin 1950. Univ. Colorado Studies, Ser. Biol. 1:29–45). Members of the genus *Plethodon* produce soft squeaks, clicks, or yelps (Harper 1930. Copeia 4:153; Mansneti 1941. Copeia 4:266), and are the most vocal of the plethodontids (Neill 1952. Copeia 195–196). On 24 August 1996 around Poplar Cove Spring at the University of Mississippi Biological Field Station located in the North-Central Hills physiographic province of Lafayette County, Mississippi, USA, an adult *Plethodon mississippi* (75 mm SVL) was found under a wooden cover board. While this individual was being observed, it produced a series of five distinctive squeaks. This event paralleled the observation of Mansneti (*op. cit.*) for *P. glutinosus* in Maryland and *P. grobmani* in Florida. The production of squeaks has also been documented for *P. grobmani* (Harper, *op. cit.*) and *P. glutinosus* in Georgia (Neill, *op. cit.*).

Although Maslin (*op. cit.*) explained the anatomical mechanisms for sound production in caudates, the function of these vocalizations is only vaguely understood. Presumably, sound production plays a role in defense against predators (e.g., Brodie 1978. Copeia 1978:127–129) or social encounters (e.g., Davis and Brattstrom 1975. Herpetologica 31:409–412).

I thank R. Austin, E. D. Keiser, and S. Marshall for their assistance in preparing this note. I also thank the Mississippi Wildlife Heritage Program for funding.

Submitted by **JEREMY L. MARSHALL**, Biology Department, University of Mississippi, University, Mississippi 38677, USA.

ANURA

ATELOPUS CHIRIQUIENSIS (Chiriquí Harlequin Frog). **MATING BEHAVIOR and EGG LAYING.** The life history of the neotropical harlequin frogs of the genus *Atelopus* has been difficult to document (McDiarmid 1971. Bull. Los Angeles Co. Mus. Nat. Hist. 12:1–66). Several natural history studies have provided a general understanding of the life cycles of some species of *Atelopus*, but significant variation in some life history parameters may exist within the genus (Duellman and Lynch 1969. Herpetologica 25:231–240; Cocroft et al. 1990. Copeia 1990:631–643; Gray and Cannatella 1985. Copeia 1985:910–917; Jaslow 1979. J. Herpetol. 13:141–145).

Descriptions of egg-laying and reproductive behaviors are few or non-existent in *Atelopus* and information given here should be useful for conservation of this genus. Starrett (1967. Herpetologica 23:195–204), Mebs (1980. Salamandra 16:65–81), and Lynch (1986. J. Herpetol. 20:126–129) gave accounts of the eggs and larvae of *A. varius*, *A. cruciger*, and *A. subornatus*. These reports provided valuable descriptive information about the eggs of *Atelopus*, but did not address the actual event of deposition and related behaviors. On 18 February 1994, we observed paired *A. chiriquiensis* adults preparing to lay eggs on the substrate of a

FAX 1-520-634-1217

swift, montane stream in cloud forest (2005–2100 m) at Las Nubes Park Headquarters of Parque Internacional La Amistad, Provincia de Chiriquí, Panamá. The climate of these western Pacific slope highlands has been classified as temperate wet and dry (Rubio 1965. Comisión del Atlas de Panamá, pp. 31–33. Dirección de Estadistica y Censo, Panama City; Koppen 1931. Grundiss der Klimakunde, pp. xii–388. Walter de Gruyter & Co. Berlin). Water temperature was 10.8°C and air temperature was 17.6°C at 1300 h. We observed at least 85 males and 12 females along a 10 m stretch of creek. All females were found in axillary amplexus and solitary males were observed trying to pry amplexed males off of the backs of females. In all cases observed, males originally amplexed were able to hang on despite attempts to dislodge them. Amplectant pairs would submerge to the stream bottom for 15–30 min. Females may have been searching for egg laying sites. Of randomly selected individuals, average female size was 43.30 mm ± 0.57 SVL and 5.32 g ± 0.31 (N = 5); males measured 31.12 mm ± 0.62 SVL and 1.99 g ± 0.24 (N = 5).We returned to the same creek at 1845 h on 20 February 1996 and found several pairs (N = 5) and solitary males (N = 5) apparently still active in the darkness.

We collected 10 live specimens for further observation at the Smithsonian Tropical Research Institute. Two days later we observed egg laying by one pair in a small plastic container partially filled with unchlorinated water; 364 unpigmented eggs were laid in two strings over the course of 8–10 h on the late evening of 22 February and early morning of 23 February 1994. Egg deposition was monitored carefully every 30–40 min and it appeared that deposition was a single continuous process. Lack of pigment in the eggs of *A. chiriquiensis* is consistent with the observations for other species of *Atelopus* (Mebs, *op. cit.*; Lynch *op. cit.;* Starrett, *op. cit.*) . Eggs were laid in a massive clutch and were impossible to separate without breaking strings. It appeared that egg laying was a single event, as the female was entirely spent afterward.

The total length of a continuous string was estimated at 36–44 cm, considering that egg densities were consistently 11–13 per 25 mm of any given segment. Individual eggs measured 2.05 mm ± 0.30 (N = 10) in diameter in a protective gel case measuring 3.63 mm ± 0.34 (N = 10) in diameter. The number and size of eggs is larger for *A. chiriquiensis* (N = 364; 2.05 mm) than reported for *A. cruciger* (N = 271; 1.6–1.8 mm) (Mebs, *op. cit.*). During egg laying, the male kicked his legs two or three times before the female would squeeze out 3–5 more eggs into each string. Such leg movements may represent tactile cues to the female to synchronize egg release with milting. Eggs were watched carefully but did not appear to develop. The eggs were fixed in 10% formalin and deposited in the Higher Vertebrate Collection at the Museum of Biological Diversity at Ohio State University (OSUMZ 5054).

In June 1994 and May 1996, EDL returned to the original breeding site and found no *A. chiriquiensis*. It is likely that eggs are deposited during the short dry season of this region and that a massive migration of adult individuals occurs toward the stream valleys as hypothesized by Lynch (*op. cit.*). During June 1994, several adult *A. chiriquiensis* were found along the Rio Candela 9 km W Las Nubes. Amplectant pairs were seen migrating toward the stream, but the density of individuals did not match that seen in the previous February at Las Nubes. Perhaps local rainfall patterns determine the timing of reproduction.

We are grateful for the assistance of A. S. Rand, T. Hetherington, R. Ibañez, J. Kink, and M. Lindquist. Financial support was provided through a Smithsonian Tropical Research Institute short-term graduate fellowship (EDL). We thank IN.RE.NA.RE. for granting wildlife permits.

HYLA MINUTA (NCN). **TADPOLE BEHAVIOR**. Heyer et al. (1975 Biotropica 7:100–111) considered tadpole predation by other tadpoles as an important ecological aspect of the tadpole communities in small, ephemeral ponds that are colonized by few anuran species and which are usually opportunistic breeders. *Hyla minuta* is widespread in Brazil, occurring in a variety of habitats. Herein, we report on the predatory behavior of tadpoles taken from a permanent pond ca. 1000 m elev. near São Bento do Sul, Santa Catarina, Brazil. The pond was fully exposed to the sun and was ca. 1.2 m at the deepest point with a dense growth of *Juncus* surrounding part of the pond. No predaceous fish were observed.

Freshly collected *H. minuta* tadpoles were placed in plastic bags for transportation. These tadpoles showed a bright red cast on the tail, appearing somewhat similar to *H. senicula*. After an hour in the bags the tail fin and tail musculature of some of tadpoles had been destroyed (Fig. 1); other individuals were bitten on the belly and died shortly thereafter. Injured individuals were attacked by the other tadpoles and were completely torn apart.

No information exists on the importance of this predatory behavior in natural habitats, however in the laboratory, *H. minuta* tadpoles (34 mm TL; stage 36) attacked and completely consumed *Physalaemus* sp. (*signifer* group, 16 mm TL; stage 33) tadpoles. The *H. minuta* tadpoles are facultatively carnivorous as they were observed to feed on commercial fish food and plant material in the laboratory.

Additional information is needed on the breeding habitats of *H. minuta*. As a facultative carnivore, *H. minuta* may better exploit food availability in each situation where it occurs, thus accounting for its widespread distribution and common occurrence.

We thank Sergio Caralho and Silva and Richard Schasse for help with field work, and W. R. Heyer for reading the manuscript.

FIG. 1. Effects of conspecific predatory behavior in *Hyla minuta* tadpoles, ranging from an undamaged individual (1) to one showing severe tail damage (4).

HYLA SANBORNI (NCN). **PREDATION**. The predation of adult anurans by invertebrates seldom has been reported in the literature (Hinshaw and Sullivan 1990. J. Herpetol. 24:196–197), although spiders may be considered one of the most important predators of small terrestrial anurans (Hayes 1983. Biotropica 15(1):74–76). Lycosid spiders are most frequently found on the banks of water bodies, where they await their prey (Wise 1993. Spiders in Ecological Webs. Cambridge University Press, New York. 328 pp.).

On 22 November 1994 at 2245 h (air temperature 22°C) in Rio Claro (22°24'S, 47°33'W), São Paulo, Brazil, a lycosid spider (*Diapontia* cf. *uruguayensis*; 9.5 mm cephalothorax and abdomen length) was observed on a 0.1 m high web in the emergent vegetation along the margin of a brook. The spider was positioned between two calling adult male *Hyla sanborni* (mean total length = 18.3 mm) separated by 0.5 m from one another. One of the frogs moved during a presumed territorial dispute, emitted an encounter call (*sensu* Wells 1977. Anim. Behav. 25:663–693) and invaded the web, where it was captured by the spider. The spider held the frog for 45 minutes, with its chelicerae introduced into the end of the frog's abdomen. At the end of this time, the frog was completely immobilized. Both frog and spider were collected and, in the laboratory, the spider was observed to eat the frog's viscera. The spider was preserved and deposited in the Departamento de Zoologia - UNESP - Sao José do Rio Preto (DZSJRP-UNESP, without catalog numbers).

We thank C. F. B. Haddad and A. Cais for suggestions on the text, and L. C. B. Renner for identifying the spider.

LITORIA INERMIS (Bumpy Rocket Frog). **REPRODUCTION**. The extent to which female frogs influence selection of amplectant partners is poorly known. While it is recognized that a female may make the primary choice of a male based on properties of his acoustic signal (Arak 1988. Behav. Ecol. Sociobiol. 22:317–327; Schwartz 1986. Ethology 73:116–127; Sullivan 1983. Anim. Behav. 31:1011–1017), female frogs, as they proceed through densely populated choruses towards their chosen partners, are undoubtedly susceptible to ambush by nearby males, and therefore may actually have little choice in their resultant mates. Few studies can be found that document amplexus as a result of female choice, and thereby actually confirm a female frog's choice of partner (see Arak, *op. cit.*).

At ca. 2200 h on 10 February 1996, while searching for breeding frogs in savanna woodland, we observed a pairing of *Litoria inermis* in a chorus ca. 40 km W Townsville, Australia (146°25'E19°25'S). A male frog was calling continuously from a small patch of bare ground between large grass tussocks. We watched for some minutes before a female approached and stopped within 10 cm of the calling male. The male called incessantly, but did not approach the female. The female then circled the calling male in a series of short low hops, and again stopped ca. 10 cm from its vocal sac. The female then made a few short hops towards the male until her snout appeared to touch the male's snout. Immediately, the male deflated his vocal sac and hopped onto the female to assume the amplexed position. Both frogs then hopped off into the moonrise.

Throughout the event, no other males approached the pair. The selected male did not make any approach towards the female until she touched his snout. The male was well within the chorus and other calling males were heard nearby. This suggests that the female selected and approached this calling male through the others. Ambush of the passing female by this or any other male was not observed. Males appeared to be evenly spaced and no satellite males were observed. While our observation represents only a single incidence, it supports the idea of amplexus initiation by female choice of reproductive partner and raises the question of the use of tactile communication to initiate amplexus between frogs.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). **PREDATION**. The Cuban treefrog (*Osteopilus septentrionalis*) of the West Indies has colonized Florida successfully over the past 40 years. The susceptibility of *O. septentrionalis* to novel predators in Florida is an open question, although predation by owls and snakes has been recorded for Florida (Love 1995. Herpetol. Rev. 26:201–202; Meshaka 1996. Florida Field Sci. 24:15; Meshaka and Ferster 1995. Florida Field Sci. 23:97–98). Here, we document predation by a new species, the common garter snake (*Thamnophis sirtalis*), on *O. septentrionalis* and present results of a field trial. Voucher specimens are housed in the Everglades Regional Collection Center in Everglades National Park, Homestead, Florida, USA.

On 21 November 1992 at 0200 h on Gumbo Limbo Trail, Royal Palm Hammock, Paradise Key, Everglades National Park, an *O. septentrionalis* ca. 40 mm SVL was offered to a *T. sirtalis* ca. 600 mm SVL that was resting 2.0 m above ground in the branches of a soapberry tree. Within 30 s of the offer, the snake grabbed the frog by its lateral aspect. Struggling and crying, the frog was ingested head-first within a few minutes. When the snake was observed 20 min later, it had not left its perch and the frog had not been regurgitated. Captive *T. sirtalis* have shown no ill effects for one week after ingesting *O. septentrionalis*.

On 19 July 1996 at ca. 2200 h we uncovered a male *T. sirtalis* (EVER 303586, 285 mm SVL) beneath a board near the buildings of a campground located near the intersection of US-1 and SW 344 Str., Florida City, Dade Co., Florida. When palped, the snake regurgitated a partially digested *O. septentrionalis* ca. 25 mm SVL.

It appears that the colonization of *O. septentrionalis* in Florida has progressed despite a list of novel predators which, like those of the West Indies (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville), are primarily ophidian.

RANA SYLVATICA (Wood Frog). **EGG MASS FEATURES** and **LARVAL BEHAVIOR.** Although *Rana sylvatica* egg masses have been described (Johnson 1987. The Amphibians and Reptiles of Missouri. Missouri Dept. Conservation, Jefferson City. 368 pp.; Wright and Wright 1949. Handbook of Frogs and Toads. Comstock Publ. Co., Ithaca, New York. 640 pp.), observations from oviposition to hatching and afterwards are lacking. Such observations were recorded as part of a translocation project (Thurow 1994. Trans. Illinois Acad. Sci. 87:83–97) in McDonough Co., Illinois, USA. Observations from at least seven years are summarized below.

Different surface/volume (S/V) ratios of frog egg masses have been correlated with average temperature and water oxygenation differences (Moore 1940. Am. Nat. 74:89–93). Moore proposed that the rounded egg masses of early breeders like *R. sylvatica* should protect better against cold, and that the thin surface film masses of later breeders like *R. catesbeiana* should aid gas exchange at warmer temperatures. However, in nature, the S/V ratio of *R. sylvatica* egg masses changes, in a way which would further increase fitness: as an object departs from a spherical shape, the S/V ratio increases. Instead of crawling forward in shallow water during oviposition like *Bufo americanus*, *R. sylvatica* stays at an underwater branch, root, or weed stem and makes minor movements. Each string of eggs folds back on itself and adheres into a globular mass that becomes turgid when the jelly imbibes water and swells. During the 2–3 weeks before hatching, the egg mass changes shape and increases its S/V ratio, presumably through softening and deterioration because of bacterial action. Less than two weeks after oviposition the flattened mass may appear as loosely coiled strings of pearls, because some of the stickiness between strands has disappeared. Further deterioration of the jelly makes a soft continuous flat mass, if not a thick film. This S/V change favors oxygen diffusion as temperatures rise from March into April.

When embryos hatch in April, the jelly mass gives protection, aided by a transient hatchling behavior. Hatchlings tend to stay in or under the jelly mass for several days, gaining shelter from predators while their swimming abilities improve. There is a temporary hatchling attraction to the jelly mass, which lasts from hours to a few days. When hatching egg masses are agitated the tadpoles swarm out in a cloud, but most return into the jelly within a few minutes. In a few days the tadpoles disperse, to rest on or below underwater leaves or branches. Later in the spring larvae tend to move to deeper water away from the pond edges. Within a few days of hatching some of the hatchlings appear to feed on their own jelly masses which have algal growth both outside and inside (Gilbert 1942. Ecology 23:215–227).

These studies were supported partly by 1986/87 non-game wildlife conservation grants from the Illinois Department of Natural Resources utilizing tax check-off funds.

SPEA MULTIPLICATA (New Mexico Spadefoot). **DEFENSIVE POSTURE.** Anurans frequently employ posture as a defensive mechanism (Duellman and Trueb. 1986. Biology of Amphibians. McGraw-Hill Book Co., New York xix + 670 pp). To our knowledge, no defensive postures have been described for western spadefoots, including *Spea multiplicata*.

On 28 May 1995 a *S. multiplicata* was found buried in moist, sandy soil under a small rock in Vogel Canyon, Otero County, Colorado, USA. Air temperature was 15°C, ground temperature was ca. 17°C. The animal was rinsed with water to wash off the sand prior to being photographed. At this time the spadefoot assumed a crouched position with the chin near the ground and the eyes closed. It remained rigid and immobile in this position for several seconds. When it began to relax, a slight touch on the snout was sufficient to induce resumption of the posture.

Crouching has been included as a defensive posture in *Scaphiopus holbrooki* by Marchisin and Andrews (1978. J. Herpetol. 12(2):151–155). C. K. Dodd, Jr. (pers. comm.) described *S. holbrooki* as tucking its body into a convex curve with eyes closed and limbs held tightly against the body. In contrast, the forelimbs of *Spea multiplicata* were not held so tightly against the body.

We thank C. Kenneth Dodd, Jr., for his assistance in the preparation of this note.

TESTUDINES

CLEMMYS MUHLENBERGII (Bog Turtle). **PARASITISM.** The larvae of certain species of flesh fly (Diptera: Sarcophagidae) are parasitic on vertebrates, and one species, *Cistudinomyia cistudinis* (Aldrich), is a fairly common parasite of box turtles (*Terrapene*) and tortoises (*Gopherus* and *Testudo*) (Knipling 1937. Proc. Entomol. Soc. Washington 39:91–101). Chidester (1915. J. Parasitol. 2:48–49) also reported an instance of parasitism, apparently by this fly, on the painted turtle (*Chrysemys picta*). We here report several instances of parasitism, apparently by *C. cistudinis*, on the bog turtle (*Clemmys muhlenbergii*) in North Carolina, USA (Table 1).

Because the parasites were either not collected or not reared to adulthood, it is impossible to identify them to species. However, those larvae that were collected were positively identified as sarcophagids and are thought to be *Cistudinomyia cistudinis* (David L. Stephan, pers. comm.), the only North American sarcophagid known to be a true parasite on adult reptiles (Knipling, *op. cit.*).

TABLE 1. Records of flesh fly parasitism in *Clemmys muhlenbergii* from North Carolina. Where retained, specimens were deposited in North Carolina State Museum of Natural Sciences (NCSM) or entomological collections of North Carolina State University (NCSU).

Date	Locality	Size and sex of turtle	Collector(s)	# of fly larvae and location on host	Fate of specimens
19 July 1977	Henderson Co., ca. 2.4 km W of Etowah	adult female	R. T. Zappalorti	1 near left shoulder	Larva removed and discarded; turtle marked and released.
19 July 1977	Henderson Co., ca. 2.4 km W of Etowah	subadult female	R. T. Zappalorti	1 in neck	Larva removed and discarded; turtle marked and released.
4 May 1985	Clay Co., ca. 9 km NE of Shooting Creek	adult male	K. M. Fahey	9 between neck and right foreleg	Larvae removed and discarded; turtle collected and died a few weeks later (NCSM 31691).
29 May 1988	Macon Co., ca. 5.3 km S of Aquone	adult male	B. J. and R. W. Johnson	17 near right rear leg	Turtle found fresh dead (NCSM 29286); larvae to NCSU.
23 June 1996	Wilkes Co., ca. 4.8 km ENE of McGrady	adult female	J. C. Beane R. A. Davis W. H. Rowland, Jr.	4 between neck and right foreleg	Turtle marked and released; larvae to NCSU.

Our observations apparently represent the first published records of parasitism on *C. muhlenbergii* by a sarcophagid fly. These flies have been known to cause death in *Gopherus* (Knipling, *op. cit.*) and *Terrapene* (Rainey 1953. Herpetologica 9:109–110). It is possible that flesh fly parasitism could be a significant, if hitherto overlooked, cause of mortality in some bog turtle populations.

We thank D. L. Stephan for identifying the larvae and providing references, K. M. Fahey and D. W. Herman for sharing information, and Ira Gambill for property access. These observations were made possible in part by "Project Bog Turtle," a funding initiative of the North Carolina Herpetological Society.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 29555, Raleigh, North Carolina 27626-0555, USA, and **ROBERT T. ZAPPALORTI,** Herpetological Associates, Inc., 2525 Dover Road—Bamber Lake, Forked River, New Jersey 08731, USA.

LEPIDOCHELYS KEMPI (Kemp's Ridley), ***CARETTA CARETTA*** (Loggerhead), and ***MALACLEMYS TERRAPIN CENTRATA*** (Carolina Diamondback Terrapin). **DIET and PREDATION**. *Lepidochelys kempi* and *Caretta caretta* feed on a variety of marine vertebrates and invertebrates (Bjorndal 1985. Copeia 1985:736–751; Dodd 1988. U.S. Fish Wildl. Serv. Biol. Rep. 88:1–110). Here I report two separate accounts of marine turtles feeding upon *Malaclemys terrapin centrata*, a species not previously reported in the diets of *L. kempi* or *C. caretta*.

On 8 June 1993, a Savannah Science Museum (SSM) research team found a dead female *L. kempi* (SSM 12640; 63.5 cm curved carapace length [CCL]; 62.5 cm curved carapace width [CCS]) at Wassaw National Wildlife Refuge, Georgia, USA. Gastrointestinal (GI) tract analysis revealed food items commonly seen from *L. kempi* specimens in Georgia waters (unpubl. data): blue crabs (*Callinectes sapidus*), spider crabs (*Libinia dubia*), stone crabs (*Menippe mercenaria*), and mud snails (possibly secondary ingestion, *Nassarius obbsoletta*). In addition to these items, two freshly eaten *Malaclemys* also were found; one of adult male size (12.2 cm estimated CCL; 7.6 cm estimated CCW; SSM 13753), and one unsexed juvenile (CCL and CCW were not taken due to condition of specimen; SSM 13754). Both *Malaclemys* were crushed at the rear of the carapace, the second suffered more severe damage than the first.

On 22 May 1996, a subadult female *Caretta caretta*, (72 cm CCL; 65 cm CCW; SSM 13758), found dead in the Wilmington River (Wilmington Island, Georgia), also had remains of *Malaclemys* within its GI tract. These were badly decomposed and thus were not measured. Examination of the *Malaclemys* remains suggests that three individuals were eaten by the *Caretta*; based on the presence of three heads, six forelimbs, and three sections of carapace still containing nuchal bones. According to head size, two individuals were of juvenile size (SSM 13755–56) and the third was the size of a large adult female (SSM 13757). Additional stomach contents of the *Caretta* were horseshoe crabs (*Limulus polyphemus*), blue crabs (*Callinectes sapidus*), knobbed whelks (*Busycon carica*), and Keiner's whelks (*Busycon keineri*).

These observations are of interest as it is assumed that *L. kempi* and *C. caretta* feed upon slow to moderately slow-moving benthic organisms. These records also suggest that fish found in stomachs of *C. caretta* and *L. kempi* may have been captured alive rather than consumed as carrion from shrimp trawler by-catch.

I thank the Georgia Department of Natural Resources (Coastal Resources Division, Brunswick), the U.S. Fish and Wildlife Service (Savannah Coastal Refuges), and all of my co-workers at the Caretta Research Project and the Savannah Science Museum.

Submitted by **MICHAEL G. FRICK**, Caretta Research Project, Savannah Science Museum, 4405 Paulsen Street, Savannah, Georgia 31405, USA.

TRACHEMYS GAIGEAE (Big Bend Slider). **REPRODUCTION.** Little information is available on clutch size in *Trachemys gaigeae*. Legler (1960. Herpetologica 16:139–140) reported clutches of 6–11 oviductal eggs in four females (169–202 mm carapace length) collected on 26 June 1959 in Chihuahua, Mexico. Here we report an unusually large clutch from a New Mexico *T. gaigeae*.

On 8 June 1988 one of us (CWP) collected a gravid female (224 mm straight-line carapace length along midline) from the north end of Elephant Butte Reservoir, Socorro Co., New Mexico, USA. The specimen was sacrificed 3–4 weeks later, dissected for tissue samples, and preserved in the Herpetology Division of the University of New Mexico Museum of Southwestern Biology (MSB 50523). Although a cursory examination indicated this specimen contained at least 10 shelled eggs (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.), a more thorough dissection revealed a clutch of 29 eggs (mostly to completely shelled), of which 24 were in the oviducts and 5 in the abdominal cavity. Mean egg length and width (post-preservation, in mm) were 37.3 ± 1.6 SD (34.5–40.3) and 22.8 ± 0.6 SD (21.5–24.0). A small (13.6 x 11.1 mm), ovoid , shelled egg also was present in one oviduct but was not included in the count of 29 full-sized eggs. In addition to eggs, there were two distinct sets of enlarged ovarian follicles which measured ca. 15 mm (N = 16) and 10–12 mm (N = 6) in diameter.

The number of full-sized eggs (29) is noteworthy in that the largest clutch reported for all species of *Trachemys* is 30 for *T. scripta callirostris* (Moll and Moll 1990. *In* Gibbons [ed.], Life History and Ecology of the Slider Turtle, pp. 152–161. Smithsonian Inst. Press, Washington, D.C.) and *T. s. elegans* (Tucker 1996. Herpetol. Rev. 27:142). The enlarged follicles suggest that this specimen could have produced an additional 1–2 clutches in 1988. Although *T. scripta* may produce 3 or more clutches per year (e.g., Moll and Moll 1990, *op. cit.*), multiple clutches in *T. gaigeae* have not been reported previously.

We thank C. S. Pease, E. Jaquez, and A. H. Price for assistance.

Submitted by **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, Endangered Species Program, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). **COLONIZATION.** The presence of freshwater turtles in landlocked aquatic habitats depends on colonization across land. Parker (1990 *In* Gibbons [ed.], Life History and Ecology of the Slider Turtle, pp. 216–222. Smithsonian Inst. Press, Washington, D.C.) studied colonization of a farm pond by *Trachemys scripta* and found that juveniles (45–90 mm plastron length [PL]) were the most frequent colonists. Here, we report an instance where hatchling (30-33 mm PL) *T. scripta* have colonized a farm pond.

One of us (JMH) has a small (ca. 0.04 ha) farm pond on his property, located in Oklahoma Co., Oklahoma, USA (35°41'11"N, 97°14'0"W). The pond is surrounded partially by a drift-fence with pitfall traps, and is isolated from other aquatic habitats by at least 500 m. Previous pitfall trapping, seining, hoop netting, funnel trapping, and observations at the study pond indicate that there were no resident turtles of any species prior to April 1996. Between April and June 1996, four hatchling *T. scripta elegans* were captured in the pitfall traps. The first three hatchlings were measured, marked, and released into the pond, whereas the last one was released into the pond without measuring or marking. The three that were meaured averaged 31.8 ± 1.16 mm PL. On 17 September 1996, we recaptured one of these hatchlings in the pond in a funnel trap baited with sardines. During the 147 days between captures this hatchling increased its PL by 14.7 mm, and more than tripled its mass (9.02–29.4 g).

The most likely explanation for this colonization is that a gravid female from a nearby pond nested close enough to the study pond to allow her hatchlings to disperse to the study pond following their emergence from the nest. Nesting migrations by freshwater turtles are common (Gibbons et al. 1990. *In* Gibbons, *op. cit.*, pp. 201–215). One function of these migrations might be to provide suitable natal habitat for emerging offspring (Congdon et al. 1987. Herptologica 43:39–54). Our observation provides evidence for such a function.

Submitted by **PAUL A. STONE** and **JOHN M. HRANITZ**, Department of Biology, University of Central Oklahoma, Edmond, Oklahoma 73034, USA.

SAURIA

ANOLIS CRISTATELLUS WILEYAE (Virgin Islands Crested Anole). **FRUGIVORY.** Anoles have long been known to eat fruit (Lazell 1972. Bull. Mus. Comp. Zool. 143:22–74) but the frequency and enthusiasm with which they do so have not often been documented. Here we report several instances of frugivory observed in the British Virgin Islands. On 5 October 1996 we watched an adult male crested anole consuming the sweet, magenta fruits of *Melocactus intortus* (Cactaceae) on Guana Island. Anoles caught during the fruiting season often defecate red or purple masses containing seeds. Previous studies of stomach contents conducted at this site have shown that fruits are not uncommon in anole stomachs (G. Perry, unpubl.; material deposited in the Texas Memorial Museum, Austin); however, this was our first observation of intentional ingestion at this site. On 11 October 1996 we observed a pair of crested anoles feeding in a patch of *Trichostigma octandra* (Phytolaccaceae) profusely in fruit with crimson berries. The fruits were about 50 cm above the ground in clusters. Access seemed to be a problem; although the anoles easily could have ridden these small, semi-vining herbs down, they did not. The female anole climbed down a small vine to consume as many berries as she could reach. The male (now Museum of Comparative Zoology 182075) attacked the berries from the edge of a large boulder. It ate all the berries it could reach, even to the extent of lunging out, disengaging its forefeet, and sprawling forward, retaining a grip on the rock only with its rear feet. When captured, this individual defecated *Trichostigma* seeds and skins in a red matrix. On dissection, the entire gut was packed with fruit.

We are indebted to Dr. George Proctor, Puerto Rico Department of Natural Resources, and Dr. Fred Kraus, Hawaii Division of Forestry and Wildlife, for identifying the plants.

Submitted by **JAMES LAZELL**, The Conservation Agency, 6 Swinburne St., Jamestown, Rhode Island 02835, USA, and **GAD PERRY**, Department of Zoology, Ohio State University, 1735 Neil Avenue, Columbus, Ohio 43210, USA.

ANOLIS STRATULUS (Saddled Anole). **NECTIVORY.** Nectar feeding has been recorded in anoles (Liner 1996. Herpetol. Rev. 27:78), but we believe it is far more commonplace and widespread than published records indicate. On 12 October 1996 we observed an adult male *Anolis stratulus* climbing on top of a shrub, *Pedilanthus tithymaloides* (Euphorbiaceae), on Guana Island, British Virgin Islands. The anole approached the shrub's flowers and proceeded to lick off drops of nectar that form on the tops of the flowers. This feeding behavior continued for over 10 min. The flowers are coral-red and the clear nectar is sweet to the taste.

We are indebted to Dr. Richard Howard, Gray Herbarium, Harvard, for confirmation of the plant's identity.

Submitted by **GAD PERRY**, Department of Zoology, Ohio State University, 1735 Neil Avenue, Columbus, Ohio 43210, USA, and **JAMES LAZELL**, The Conservation Agency, 6 Swinburne St., Jamestown, Rhode Island 02835, USA.

DRACAENA PARAGUAYENSIS (Paraguayan Caiman-lizard). **COURTSHIP.** The neotropical genus *Dracaena* (Sauria, Teiidae) contains two species of large-bodied lizards, both having diurnal, semiaquatic and semiarboreal habits, and known to feed mainly on freshwater snails (Vanzolini and Valencia 1966. Arq. Zool. 13:7–35).

Little information is available on the natural history of *D. paraguayensis* Amaral, which seems to be restricted to the seasonally flooded terrains of the Paraguay River basin, middle South America. Individuals of this species are seen commonly in selected wet habitats of the Pantanal wetlands, western Brazil (pers. obs.). Local inhabitants believe it to be venomous, as already noted by Amaral (1950. Copeia 1950:281–284), and refer to it as "bírbola" (a mis-pronounciation of the Portuguese word "víbora," which means viper).

On 27 January 1990, at 1005 h, at Santa Ines Ranch (ca. 16°30'S, 56°45'W) in the northern Pantanal, I found two *D. paraguayensis* interacting in shallow water (20 cm depth; 33.5°C water temperature). The lizards were discovered because of the loud puffs produced by one of them towards the other. I first heard the sound at a distance of about 7 m. As I approached, I could see them moving slowly among the dense aquatic vegetation (predominantly Pontederiaceae and Cyperaceae). It was evident that the puffs were being directed from a male to a female, as part of a courtship sequence. Movements then performed by the lizards may be summarized as follows: 1) Female moving continuously, at an approximate speed of 2 m/min; 2) Male following the female closely, sometimes trying to mount her. While moving, the male repeatedly puffed (about once each second), concomitantly inflating his dewlap. Occasionally, the male bit the female's tail at the base and lashed his own tail into the water; 3) When the female ceased locomotion, the male immediately positioned his body parallel, over and slightly behind relative to hers. The male then began to slide, from side to side, along the longitudinal axis of the female's body. Noisy puffs were produced repeatedly by the male during this phase too, presumably while mating; 4) The couple remained motionless for about 30 s, then moved away and out of my view.

Puffing behavior in courting lizards was known previously only for the genus *Tupinambis* (Carpenter and Ferguson 1977. *In* Gans and Tinkle [eds.], Biology of the Reptilia. Vol. 7, Ecology and Behavior A, pp. 335–554. Academic Press, New York) and was considered the most striking feature in the courtship of *T. teguixin* (Lopes 1986. Biologia reprodutiva e comportamento do teiu, *Tupinambis teguixin* (Linnaeus, 1758) em cativeiro (Reptilia, Teiidae). MsC thesis, Sao Carlos, 131 pp.). Most other behavioral units here reported as part of the courtship in *D. paraauayensis* are similar to those observed in *T. teguixin* by Lopes (*op. cit.*), except for tail lashing. On the other hand, I did not observe the frequent tongue protraction and mating and postmating behaviors of the kind described for *T. teguixin* (Lopes, *op. cit.*). It is possible that they also occur in the courtship of *Dracaena*, and that only a part of the entire courtship sequence of *D. paraguayensis* was witnessed by me.

Puffs sound different during courtship and as a defensive behavior (= "hiss", sensu Greene 1988. *In* Gans and Huey [eds.], Biology of the Reptilia. Vol. 16, Ecology B, pp. 1–152. Alan R. Liss, New York) in *T. teguixin* (Lopes, *op. cit.*). I also observed that, when attacked, *D. paraguayensis* produces more prolonged puffs in comparison with those produced during courtship.

The presence of courtship puffs in *Dracaena* and *Tupinambis* further emphasizes the close relationship between these two macroteiid genera, as suggested by Vanzolini and Valencia (*op. cit.*) and Presch (1974. Bull. So. California Acad. Sci. 73:23–32), based on morphological features.

I thank I. Sazima, A. S. Abe, and C. F. D. Rocha for helpful comments on an earlier version of the manuscript; B. L. Miranda for assistance in fieldwork, and O. Cid for facilities at the Santa Inês Ranch. Funds were provided in part by CNPq (grant 831105/89-5) and FEMA-MT (Fundação Estadual de Meio Ambiente, Mato Grosso). Fieldwork was conducted while I was a graduate student at UNICAMP (Universidade Estadual de Campinas, Sao Paulo).

Submitted by **CHRISTINE STRUSSMANN**, Rua Antonio Dorileo 508 apto. 34, 78085-600 Cuiaba, Mato Grosso, Brazil.

EUMECES SUMICHRASTI (NCN). **BROOD.** During the evening of 3 April 1992, a violent thunder and windstorm felled a large breadnut tree *(Brosimum alicastrum)* at the Caracol archaeological site (16°45'N, 89°7'W) in the Chiquibul National Park, Belize. The following morning, as the tree was being cut and sectioned for disposal, a clutch of eggs and an adult *Eumeces sumichrasti* were discovered in a cavity which would have been ca. 20 m above ground. This was considerably higher than nest sites described for *Eumeces fasciatus* (Cooper et al. 1983. Herpetol. Rev. 14:65–66) which were ca. 1 m above ground, with one nest as high as 10 m. The cavity containing the nest was located in a crotch formed by five branches. The cavity opening was 125 x 201 mm and was filled with coarse, rotting wood debris, similar to that described for *E. fasciatus* (Hecnar 1994. Canadian J. Zool. 72:1510–1516).

The presumed female (92 mm SVL; 190 mm total length; 18.0 g) and 11 eggs were recovered, apparently uninjured by the tree fall. This clutch size was slightly larger than the 5–10 observed for *E. fasciatus* by Cooper et al. (*op.* cit.). The eggs were distributed throughout the coarse woody debris; six were close to each other, buffered by debris and the remaining five were more widely scattered throughout the debris. Mean egg measurements were 15 x 11 mm and mean weight was less than 1 g.

The skink was relocated with six eggs and a handful of the woody debris to the crotch of another tree, ca. 1.5 m above ground, in adjacent tropical forest. It remained on top of the eggs in a loose semi-circular brooding position, reported as common in other species of *Eumeces* (Noble and Mason. 1933. Amer. Mus. Novitates 619). The remaining five eggs were scattered throughout a handful of the woody debris and placed in a plastic bag. The top of the bag was left loosely open to allow ventilation but retain moisture. The bag was placed in a shaded area in a camp hut. The skink was checked twice during the day of relocation. It remained with eggs in the new nesting location. The following day, the relocated nest was intact although the adult was absent.

On 9 April, four of the five eggs in the plastic bag hatched. The fifth egg appeared dry and later examination showed a less developed embryo with yolk sac. An examination of the relocated nest showed that all six eggs had apparently hatched, as evidenced by the remains of empty eggshells. The adult and hatchlings were not observed.

Mean measurements of the four captive hatchlings before release were as follows: 26 mm SVL; 70 mm total length; 0.67 g.

The base color of the hatchlings was black with vivid blue tails. The dorsal surface of the snout was marked with an orange diamond shape between the nostrils and an orange spot between the eyes. Three lines extended the length of the body, one from either nostril and the third from the diamond mark, passing through the interorbital spot. The three lines gradually shaded from orange on the head, to yellow to blue at the tail. A cream stripe extended laterally from the jaw, merging to blue at the tail. Ventral surfaces were cream except for the blue tail.

The Wildlife Conservation Society, Bowen & Bowen Ltd., and the Terra Foundation provided major project support during the time these observations were made. Permits to work at Caracol were obtained from the Forestry Department of Belize. I am grateful to S. Johnson of the Wildlife Conservation Society library for providing relevant literature. B. W. Miller provided field assistance and helpful comments. M. J. O'Farrell and J. R. Meyer reviewed an earlier version of the manuscript.

Submitted by **CAROLYN M. MILLER**, Wildlife Conservation Society, Gallon Jug, Belize.

MABUYA MACRORHYNCHA (NCN). **REPRODUCTION.** Data on the natural history of *Mabuya macrorhyncha* (Scincidae) are scare (Vanzolini and Rebouças-Spieker 1976. Pap. Avul. Zool. 29:95–109). On 17 October 1995, a female *M. macrorhyncha* was captured at Queimada Grande Island (24°29'S, 46°41'W), on the southeastern coast of Brazil. The lizard was maintained in a glass terrarium (35 x 20 x 25 cm) with a mixture of *Sphagnum* and plant debris as substrate. Water and direct sunlight were available, and the lizard was fed crickets and cockroaches. On 6 February 1996, the female (SVL = 76.0 mm) gave birth to three offspring (SVL = 33.0, 33.5, and 34.3 mm). The young appeared healthy and were able to eats small crickets and cockroaches some hours later.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **GROWTH**. *Phrynosoma cornutum* is a Texas threatened species and a federal species of concern. However, information concerning the basic biology of *P. cornutum* is limited.

We marked and released *P. cornutum* from March 1991 to October 1994 on the Chaparral Wildlife Management Area (28°20'N, 99°30'W) in southern Texas, USA. Lizards were captured by road cruising, marked by toe-clipping and passive integrated transponders, and released at site of capture. Recaptures permitted the calculation of growth rates. Daily growth is reported as mm snout-vent length (mm SVL/day) between recaptures for each individual within the same year, and then averaged for juveniles and adults. Lizards between 50 and 75 mm SVL were classified as juveniles, and those > 75 mm SVL were considered adults. Growth rates for adult horned lizards during hibernation were calculated as the average mm SVL of lizards captured in late autumn (September and October) and recaptured in early spring (March and April) of the next year.

We collected 689 *P. cornutum* during the study. Of these, 42 lizards were captured on 98 occasions; 34 were captured twice, 4 were caught three times, 3 were captured four times, and 1 lizard was caught 6 times. Of those that were captured more than once, 3 were classified as juveniles and 39 were considered adults. We did not capture any lizards < 61 mm SVL. Mean growth of juveniles (1M:2F) was 0.527 mm SVL/day (SE = 0.230; N = 3). Mean growth for adults was 0.391 mm SVL/day (SE = 0.176; N = 40). There was no difference (t = -0.697; df= 38; $P = 0.490$) in growth rates between adult males and females (0.248 ± 0.086 mm SVL/day; N = 17 and 0.497 ± 0.300 mm SVL/day; N = 23, respectively). Fifteen adults (8M:7F) were captured in late autumn and recaptured in early spring of the next year (interval between measurements = 160–242 days). Mean growth of adults during hibernation was 0.036 mm SVL/day (SE = 0.010; N = 15).

We thank the personnel of the Chaparral WMA for their assistance with data collection. Financial assistance was provided by Texas Parks and Wildlife Department and the Horned Lizard Conservation Society.

* Present address: Caesar Kleberg Wildlife Research Institute, Texas A&M University-Kingsville, Kingsville, Texas 78363, USA.

PHYLLODACTYLUS XANTI (Leaf-toed Gecko). **REPRODUCTION.** The purpose of this note is to report on a histological examination of gonads from 36 *P. xanti* from southern California, USA. Specimens were examined from the Natural History Museum of Los Angeles County (LACM), Museum of Vertebrate Zoology (MVZ), and San Diego Natural History Museum (SDSNH). Imperial County: LACM 52617, 93854–93856, 93858, 93860, 93863, 93865–93866, 93867–93870, 93872, 93874–93875, 99457, 125332, 126013. SDSNH 34725, 49879–49881, 58588, 58922, 62115. Riverside County: MVZ 71085. San Diego County: LACM 93876–93877, 93879, 14003,143743–143744. MVZ 72588, 98164. SDSNH 43786. The left gonad was removed and embedded in paraffin for histological examination. Sections were cut at 5 µm and stained with hematoxylin and eosin counterstain. Histology slides were deposited at LACM. My female sample (N = 18) had a mean SVL of 52.8 mm ± 2.5 SD (range 47–57 mm); male sample (N = 18) mean SVL = 50.3 mm ± 4.3 SD (range 42–56 mm). Testes were classified (sample size in parentheses) as to their spermatogenic state: regressed (spematogonia present, no spermatocytes); recrudescent (renewal of germinal epithelium with spermatocytes, but no sperm); spermiogenesis (sperm formation in progress); January (1) recrudescence; February (4) spermiogenesis; March (1) spermiogenesis; April (6) spermiogenesis; May (1) spermiogenesis; August (1) regressed; October (1) recrudescent; November (2) 1 recrudescent, 1 spermiogenesis; December (1) spermiogenesis. The smallest reproductively active male (spermiogenesis in progress) measured 42 mm SVL. The presence of November, December and February spermiogenic males raises the possibility that reproductive activity may commence in winter. Ovaries were classified (sample size in parentheses) as to their reproductive state: inactive (no yolk deposition); vitellogenic (yolk deposition in progress); enlarged follicles (> 3 mm diameter); oviductal eggs. February (1) inactive; March (1) inactive; April (5) 2 inactive, 3 vitellogenic; May (5) 1 inactive, 1 enlarged follicles, 3 oviductal eggs (1 egg in 1, 2 eggs in each of 2); September (2) inactive; October (2) inactive; November (1) inactive; December (1) inactive. The smallest reproductively active female (enlarged follicles) measured 49 mm SVL. The presence of oviductal females in May

(range 1–2 eggs) reconfirms previous reports (Behler and King 1988. The Audubon Society Field Guide to North American Reptiles and Amphibians, Alfred A. Knopf, New York, New York. 743 pp.; Stebbins 1985. A Field Guide to Western Reptiles and Amphibians, Houghton-Mifflin Co., Boston, Massachusetts. 336 pp.).

I thank Robert L. Bezy (Natural History Museum of Los Angeles County), Harry W. Greene (Museum of Vertebrate Zoology, University of California), and Gregory K. Pregill (formerly of the San Diego Natural History Museum) for permission to examine *P. xanti*.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA.

SERPENTES

AGKISTRODON CONTORTRIX CONTORTRIX (Southern Copperhead). **DIET**. Copperheads are known to feed on a variety of arthropod species, including moth caterpillars and cicada nymphs (Uhler et al. 1939. Trans. 4th North Amer. Wildl. Conf., pp. 605–622), dragonflies and millipedes (Brown 1979. Brimleyana 1:113–124), and mantids and grasshoppers (Hamilton and Pollack 1955. Nat. Hist. Misc. 140:1–4).

During the evening of 25 May 1996 I collected a male *Agkistrodon c. contortrix* (46.5 cm SVL) on County Road 119, 0.5 miles W of County Road 277, Jasper County, South Carolina, USA. On 2 June 1996 this snake disgorged a deeply-pleated light brown mass measuring 3.6 x 1.7 cm. Douglas Ferguson (USDA Systematic Entomology Laboratory) identified the mass as being the cocoon of a luna moth (*Actias luna*). Because the moth had not emerged (based on the lack of an opening and the presence of pupa remains within the cocoon), the most likely scenarios is that the snake consumed the cocoon, digested the contents, and disgorged the indigestible cocoon. The cocoon has been deposited in the entomology collection of the U.S. National Museum of Natural History.

Submitted by **CHUCK SMITH**, Department of Biology, The University of South Carolina, Columbia, South Carolina 29208, USA.

BOIGA IRREGULARIS (Brown Tree Snake). **INCUBATION and DIET.** *Boiga irregularis* is an exotic species on Guam that has been responsible for the extirpation or substantial reductions of Guam's forest birds (Savidge 1987. Ecol. 68:660–668), fruit bats (Wiles 1987. Pac. Sci. 41:148–157), and native lizard species (Rodda and Fritts 1992. J. Herpetol. 26:166–174). Despite intensive study, only one report of a successful incubation of a clutch of *B. irregularis* eggs has appeared in the literature (McCoid 1994. Herpetol. Rev. 25:69–70). We report here on the successful incubation of a second clutch on Guam and the diet accepted by the hatchlings.

On 18 May 1995 a *B. irregularis* (1.7 m total length) captured on Andersen Air Force Base deposited a clutch of 8 adherent eggs. Three of the eggs shriveled within a few days of deposition. The remaining 5 eggs were incubated at ambient temperature (ca. 25–30°C) and humidity (>95%) in a glass terrarium using slightly moistened casuarina needles (*Casuarina equistefolia*) as a substrate. After 74 days (31 July 1995), an egg that was discolored was opened, revealing a well-formed, live embryo 142 mm total length. After 120 days the eggs became noticeably dimpled (17 September 1995). The remaining 4 eggs pipped and the 4 snakes emerged on 21–22 September 1995 (125–126 days incubation period). This incubation period was 31–32 days longer than the 94 days reported by McCoid (1994, *op. cit.*).

We maintained two hatchlings (397 and 402 mm total length) in captivity. Three species of geckos, *Leptodactylus lugubris, Hemidactylus frenatus*, and *Gehrya mutilata,* were offered to the snakes, but only *L. lugubris* between 25–30 mm SVL were consumed. Size is apparently the basis for this selectivity, as we have not found juvenile *H. frenatus* or *G. mutilata* as small as 25–30 mm SVL and specimens of *L. lugubris* exceeding 30 mm SVL were not consumed. We also presented the snakes with small grasshoppers (25 mm total length), and on four occasions, they were consumed. A larger praying mantis (50 mm) was also offered, but not consumed. To our knowledge, this is the first record of *B. irregularis* on Guam deliberately consuming insects. Savidge (1988. J. Herpetol. 22:275–282) concluded that the insects (all <10 mm total length) found in larger *B. irregularis* (>600 mm SVL) resulted from incidental intake through consumption of lizards. However, our observations suggest a possible role for insects as prey for small *B. irregularis*. In some situations, control and containment efforts for *B. irregularis* involving prey base reductions may have to consider this previously unrealized prey item for young snakes.

Submitted by **MICHAEL A. LINNELL, DANIEL V. RODRIGUEZ**, USDA/APHIS/ADC, 1060 Route 16, Suite 103-C, Barrigada Heights, Guam 96921, USA, **RICHARD E. MAULDIN** and **RICHARD M. ENGEMAN**, Denver Wildlife Research Center, P.O. Box 25266, Denver, Colorado 80225-0266, USA.

BOTHROPS PRADOI (Prado's Lancehead). **UNUSUAL MORTALITY.** Snakes sometimes take prey that are too large to swallow; such prey may be regurgitated (Sazima and Martins 1990. Mem. Inst. Butantan 52:73–79) or may kill the snake (Howard 1949. Copeia 1949:289; Godley 1980. Ecol. Monogr. 50:411–436). In July 1995, while walking in the restinga of Cumuruxatiba in southernmost Bahia State, Brazil (17°37'S; 39°33'W), one of us (RV) found a dead female *Bothrops pradoi* (61.5 cm SVL; 71 cm total length) on the ground. The snake had a partially ingested adult male (90 mm SVL; 22 mm maximum diam; 66 mm maximum circunference) collared lizard, *Tropidurus torquatus,* in its mouth. The lizard had been ingested head first, up to the anterior margin of the hind legs, and the mouth of the snake was greatly distended. Gape width of the snake was 19 mm after the lizard was removed.

In the laboratory, we carefully checked the snake's body under a stereomicroscope, but detected no sign of injury. We also examined a radiograph of the snake and found that its skull and spinal column were intact. We were not able to define the cause of the snake's death, but we cannot ignore the possibility of asphyxia. The snake was a small adult and the lizard was comparatively large, with strongly keeled and imbricated dorsal scales, which would make the lizard difficult to swallow or regurgitate.

We thank the personnel of the Image Service of the Hospital Pedro Ernesto/UERJ for the radiographs of the snake. Ivan Sazima and P. R. Manzani confirmed the identification of the snake. The former also provided helpful comments on the manuscript. CFDR benefited from a research grant (process No.300819/94-3) from the Conselho Nacional do Desenvolvimento Científico e Tecnológico (CNPq).

IMANTODES CENCHOA (Chunk-Headed Snake). **REPRODUCTION.** Reproductive aspects of *Imantodes cenchoa* are poorly documented. We report on a clutch of eggs and hatchlings from a snake captured in primary forest in the Amazonian region (Reserva Extrativista do Alto Juruá, Acre, Brazil; 8°59'S, 72°43'W). At 0700 h on 25 January 1996, a female *I. cenchoa* (ZUEC 1922; 634 mm SVL; 910 mm total length [TL]) was collected on shrubs (1 m height) and subsequently maintained in a terrarium. This female laid two eggs (36.0 and 36.5 mm long; both 15.0 mm wide), one each on 26 and 27 January. The eggs were removed and incubated in a plastic jar with moist vermiculite. After 74 days (daily temperature range 25–31°C; ca. 90% humidity), both eggs hatched. Hatchling data: ZUEC 1936, 245 mm SVL; 340 mm TL; ZUEC 1937, 242 mm SVL; 335 mm TL; both weighed 2 g. The specimens are in the collection of the Museu de História Natural, Universidade Estadual de Campinas (ZUEC).

We thank I. Sazima and Emygdio L. A. Monteiro Filho for comments on the manuscript.

PHILODRYAS PATAGONIENSIS **(NCN). DIET**. *Philodryas patagoniensis* is a semi-arboreal species that occurs in a variety of habitats in Brazil, Bolivia, Paraguay, Argentina and Uruguay (Peters and Orejas-Miranda 1986. Catalogue of the Neotropical Squamata. Part I - Snakes, 2nd ed. Smithsonian Inst. Press, Washington, 174 pp.). Records of the food and foraging behavior of this snake in the wild are scarce (Sazima and Haddad 1992. *In* Morellato (ed.)., História Natural da Serra do Japi, pp. 212–236. Editora da Unicamp/Fapesp, Campinas; Vanzolini 1948. Rev. Brasil. Biol. 8:308–311). Here we report our records of a mammal, a lizard, and nestling birds taken as food in the wild by *P. patagoniensis* in restinga habitat of Barra de Maricá (22°57'42"S, 42°51'35"W), ca. 38 km E of Rio de Janeiro, Brazil.

On 13 January 1996 (0630 h) two of us (LPG and GDAC) found an adult female *P. patagoniensis* resting ca. 80 cm above ground, stretched on the branches of a scrubby thicket. The snake showed a remarkable volume in its body, and we suspected that it might have eaten a bird from a nearby nest, so we collected it for analysis of stomach contents. Dissection revealed that the snake had ingested a sub-adult *Metachirus nudicaudatus* (brown four-eyed opossum; Didelphidia, Marmosidae). The prey had been swallowed head-first and was nearly intact (Fig. 1). The snake measured 82 cm SVL (113 cm total length), and weighed 202 g (excluding the prey). The prey weighed 112 g immediately after being removed from the snake's stomach. Also found in the digestive tract of the snake were the tail and forelimb of a scincid lizard, *Mabuya agilis*. These specimens were deposited in the Department of Vertebrates of the Museu Nacional do Rio de Janeiro (snake and lizard (MNRJ 4739), opossum (MN 43077)) .

Predation on bird nestlings occurred on 19 January 1995 (midday), and involved a widespread bird species, *Coereba flaveola* (bananaquit; Passeriformes, Emberezidae). On this occasion, LPG and GDAC were attracted by the calls of nestling *C. flaveola* to a nest ca. 90 cm above ground among thorns in the bifurcation of an isolated cactus in a small clearing. A *P. patagoniensis* had its head and neck inside the globular nest. As the snake moved a little, the corpse of a young bird dropped from the nest. The snake held another nestling in its mouth. The snake carried this dead nestling as it descended to the ground and moved into the nearest thicket, but let it fall midway to the thicket. Another young bird survived the attack, apparently not injured, and remained in the nest.

None of these prey species previously have been reported in the diet of *P. patagoniensis*.

We thank Carlos F. D. Rocha, Bret M. Whitney, Leila M. Pessoa, Richard Sachsse, Rui Cerqueira, Sérgio P. C. e Silva, and Ulisses Caramaschi for commenting on this note and providing additional information. The snake was identified by Ulisses Caramaschi, the opossum by João Alves de Oliveira, and the lizard by Carlos F. D. Rocha. Érika F. Pereira helped in field work. Maria A. S. Alves benefited from a research grant (process no. 301524/88-2) provided by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq).

TANTILLA PLANICEPS (California Black-headed Snake). **PREDATION.** At ca. 1900 h on 15 May 1982, I observed an adult loggerhead shrike (*Lanius lucovicianus*) with a juvenile *Tantilla planiceps* in its beak. The shrike was perched on the top strand of a barbed-wire fence that paralleled a road. The snake was moving, indicating it had been captured recently. The observation was made with 10x binoculars and lasted 5–10 s, after which the bird flushed. Field conditions were clear, calm, and warm. The habitat was grassland along Corral Hollow Road, Alameda Co., California, USA, 0.7 road mile W of the Alameda-San Joaquin Co. line.

Loggerhead shrikes eat invertebrates and small vertebrates (Peterson 1961. A Field Guide to Western Birds. Houghton Mifflin Co., Boston, Massachusetts, 309 pp.). This record may represent the first published account of a loggerhead shrike preying upon *Tantilla* (C. R. Mahrdt, unpubl. data).

I thank Robert Hansen for reviewing this note and Clark Mahrdt for sharing his extensive knowledge on the diet of the loggerhead shrike.

Submitted by **ED ELY**, Field Associate, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94116, USA.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 28, Number 1 (March 1997).

CAUDATA

AMBYSTOMA BARBOURI (Streamside Salamander). USA: TENNESSEE: Davidson Co: Nashville, Green Hills area, stream near Hillsboro High School. 5 March 1967. David H. Snyder. Austin Peay State University Museum of Zoology (APSU 1969). Verified by William H. Redmond. Non-gravid, adult female (SVL 73 mm); Jackson Co: Hix Hollow. 3 March 1973. T. Florence. Middle Tennessee State University Herpetological Collection (MTSU 326C, 327C). Verified by David H. Snyder. Juveniles (SVL 40 mm and 45 mm); Rutherford Co: ca. 1.1 km south of Tenn. Rt. 96 in field east of Rucker Lane. 2 October 1996. M. Brown. Middle Tennessee State University Herpetological Collection (MTSU 325C). Verified by David H. Snyder. Juvenile (SVL 44 mm). Originally identified as *Ambystoma texanum*, these specimens (reidentified based on tooth morphology and internaral distance) represent the first records of *A. barbouri* from Tennessee (Redmond and Scott 1996, Atlas of Tennessee Amphibians. Center for Field Biol. Austin Peay St. Univ. Misc. Pub. No. 12. 94 pp.) and extend the known range of the species ca. 170 km SW from Russell County, Kentucky (Kraus and Petranka 1989, Copeia 1989:94–110) into the Central Basin physiographic region of Tennessee. Redmond's and Scott's (*op. cit.*) Davidson and Jackson county records for *A. texanum* are therefore invalid and should be deleted from their Tennessee distribution map for this species.

Submitted by **A. FLOYD SCOTT**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA, **BRIAN T. MILLER** and **MATTHEW BROWN**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA, and **JAMES W. PETRANKA**, Department of Biology, University of North Carolina at Ashville, North Carolina 28804, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: GEORGIA: Marion Co: 16 km SW Buena Vista (32°10'N, 84°35'W). 8 January 1997. Bob Herrington. Georgia Southwestern State University Vertebrate Collection 6375. Verified by Marilyn Herrington. County record; represents a 150 km range extension from the nearest record in Decatur County, Georgia (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp). Specimen is one of three collected by drift fences placed in a hardwood, floodplain forest bordering the Kinchafonnee Creek.

Submitted by **BOB HERRINGTON**, Department of Biology, Georgia Southwestern State University, Americus, Georgia 31709, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: NORTH CAROLINA: Stokes Co: 4 km W Prestonville along Snow Creek. 11 April 1997. Dennis W. Herman, Jeffrey C. Beane, Ann B. Somers, and Robert A. Davis. North Carolina State Museum of Natural Sciences (NCSM color slides JCB 97-587). Verified by Alvin L. Braswell. Adult photographed and released at landowner's request and due to protected status in state. New county record; fills gap between Rockingham and Surry counties (NCSM files).

Submitted by **JEFFREY C. BEANE** and **DENNIS W. HERMAN**, North Carolina State Museum of Natural Sciences, P.O. Box 29555, Raleigh, North Carolina 27626-0555, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). GEORGIA: Burke Co: DiLane Wildlife Management Area. 22-28 April 1996. UGAMNH 32649-32652. Verified by M. E. McGhee and J. Jensen; Jones Co: Piedmont National Wildlife Refuge, 4.8 km NNW Headquarters. 29 August 1979. UGAMNH 15426. Verified by M. E. McGhee and J. Jensen; Piedmont National Wildlife Refuge, Little Falling Creek. 20 February 1980. UGAMNH 15246. Verified by M. E. McGhee and J. Jensen; Morgan Co: 0.8 km S US Rt. 278 on Co. Rd 164. 3 April 1980. UGAMNH File Record. Verified by L. J. Vitt and L. Logan; Putnam Co: Oconee National Forest, 0.5 km SW Rock Eagle Monument. 1 February 1997. UGAMNH 32423. Verified by M. E. McGhee and J. Jensen.

Submitted by **JOSHUA LAERM**, Museum of Natural History, University of Georgia, Athens, Georgia 30602, USA, **DENISE A. MAIDENS** and **LYNN LEWIS**, Daniel B. Warnell School of Forest Resources, University of Georgia, Athens, Georgia 30602, USA.

TARICHA GRANULOSA (Roughskin Newt). USA: IDAHO: Latah Co: private pond adjacent to S side of Four Mile Road, 3.5 km E Viola. 20 March 1997. Ryan J. Monello. Washington State University Charles R. Connor Museum (CRCM 97-17). Verified by Kevin Pullen. Specimen was collected from a reproducing population, 2.4 km NNE of only previous collection site (Nussbaum and Brodie 1971, Herpetologica 27:260–270). Prior to collection, only one specimen had been recorded in the past 23 years (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. The University Press of Idaho, Moscow. 332 pp.). Two additional populations have been found in nearby private ponds. All three populations appear to be comprised of relatively few animals.

Submitted by **RYAN J. MONELLO** and **R. GERALD WRIGHT**, Department of Fish and Wildlife Resources, University of Idaho, Moscow, Idaho 83844-1136, USA.

ANURA

CHACOPHRYS PIEROTTI (Lesser Chini Frog): BOLIVIA: TARIJA: Provincia Gran Chaco: Villa Montes, 21°16'S, 63°28'W. 7–27 January 1981 and February 1982. H. Meier. Zoologisches Forschungsinstitut und Museum Alexander Koenig Bonn (ZFMK 32584, 36447). Verified by W. Böhme. First record for Bolivia (De la Riva 1990, Boll. Mus. Reg. Sci. Nat. Torino 8:261–319).

Submitted by **JÖRN KÖHLER**, Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, D-53113 Bonn, Germany.

HYLA REGILLA (Pacific Treefrog). USA: CALIFORNIA: IMPERIAL CO: All American Canal near El Centro, 32°47'N, 115°36'W. elevation 11 m below sea level. 27 March 1959. J. Berry. LACM 144117–18. Verified by Kimball L. Garrett. Extends the range far into the Lower Colorado River Subdivision of the Sonoran Desert and to below sea level (Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.). This new county record is ca. 85 km ESE of the previously reported locality at Scissors Crossing, San Diego County (Jameson et al. 1966, Proc. California Acad. Sci. 33:591) and ca. 115 km SE of the locality at Pushwalla Palms, Riverside County, California (Stebbins, *op. cit.*).

Submitted by **ROBERT L. BEZY**, Amphibians and Reptiles, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA, and **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA.

LEPIDOBATRACHUS LAEVIS (Budgett's Frog): BOLIVIA: TARIJA: PROVINCIA GRAN CHACO: Villa Montes, 21°16'S, 63°28'W. 23 February 1986. H. Meier. Zoologisches Forschungsinstitut und Museum Alexander Koenig Bonn (ZFMK 44733). Verified by W. Böhme. First record for Bolivia (Faivovich 1994, Acta Zool. Lilloana 43:105-115).

Submitted by **JÖRN KÖHLER**, Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, D-53113 Bonn, Germany.

LITORIA AUREA (Green and Golden Bell Frog). TERRITORY OF WALLIS AND FUTUNA: WALLIS ('UVEA) ISLAND (13°18'S, 176°12'W). 19 December 1996. Helene Guegan. Jens V. Vindum. CAS 202722. Verified by Jens Vindum. First confirmed record for this French Pacific territory. Gill (1995, Rec. Auckland Inst. Mus. 32:55–61), who provided the first and only review of the herpetofauna of Wallis ('Uvea) Island, noted that frogs, "said to be the Australian species *Litoria aurea*" had been reported from several lakes on the island, but did not examine specimens or confirm this identification. Frogs were apparently introduced into Wallis ca. 1930 by Georges Renaud, a surgeon and French administrator, in order to control insects (Anonymous 1991, Au Pays des Trois Royaumes. Association Pacifique, Paris.). The geographic origin of the frogs is uncertain as Renaud had connections to Australia and the New Hebrides (Vanuatu), as well as to New Caledonia. However, the extensive political, economic, and transportation links between New Caledonia and Wallis strongly suggest that the animals originated there. New Caledonia has previously been proposed as the source for the subsequent introduction of *L. aurea* into Vanuatu (Tyler 1975, Copeia 1975:355–356).

Submitted by **AARON M. BAUER**, Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085-1699, USA, **ROSS A. SADLIER**, Department of Herpetology, Australian Museum, 6-8 College Street, Sydney, New South Wales 2000, Australia, and **JEAN CHAZEAU**, ORSTOM Centre de Nouméa, B. P. A5, Nouméa, New Caledonia.

PLEURODEMA TUCUMANA. ARGENTINA: JUJUY: PARQUE NACIONAL CALILEGUA, DEPARTAMENTO LEDESMA : Río Yuto (550 masl) 200 m from the Park border (23°50'S, 64°50'W) 9 January 1996. Marcos Vaira. Museo de Ciencias Naturales Universidad Nacional de Salta (MCN 347). Verified by E. O. Lavilla. Two males calling in the muddy shore of a temporary pond filled by rainwater. First province record; extends known range ca. 145 km N from former records in Joaquin V. Gonzalez, Salta [Cruz et al. 1992, Acta Zool. Lilloana 42(1):101–107]. First record for the species in a Subtropical Montane Forest.

Submitted by **MARCOS VAIRA**, Museo de Ciencias Naturales. Universidad Nacional de Salta, Mendoza 2, 4400 Salta, Argentina.

PSEUDACRIS TRISERIATA (Western Chorus Frog). USA: NEW MEXICO: CIBOLA CO: Pueblo of Laguna, 7.2 km N of Encinal, White Springs (SW 1/4 NW 1/4 Sec. 15, T11N, R6W), ca. 2330 m elev. 19 May 1997. S. E. Carr. University of New Mexico Museum of Southwestern Biology (MSB) 60771. Verified by Don S. Sias. Second record for San Mateo Mountains and confirms presence in this area of west-central New Mexico. Gehlbach (1965, Proc. U.S. Natl. Mus. 116:274) reported a specimen (CU 6338) from "Mark Elkin's Ranch, Mt. Taylor" (= Elkins Camp, Sec. 11, T12N, R7W) which was not mapped by Degenhardt et al. (1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.). Specimen provisionally assigned to *P. triseriata;* taxonomic status of New Mexico populations is unresolved.

Submitted by **STACEY E. CARR**, Department of Natural Resources, Pueblo of Laguna, P.O. Box 194, Old Laguna, New Mexico 87026, USA, **JAMES N. STUART** and **WILLIAM G. DEGENHARDT**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

TESTUDINES

CLEMMYS GUTTATA (Spotted Turtle). USA: WEST VIRGINIA: HAMPSHIRE CO: Edwards Run Wildlife Management Area (ERWMA), 3 km N Capon Bridge. 1992–1995. Three turtles were captured and released at ERWMA: an eight year old male (carapace length 99 mm) on 15 August 1992, an unknown age and sex adult turtle on 5 May 1992, and a five year old juvenile (carapace length 74 mm) on 17 September 1995. Photographs of these are catalogued in the West Virginia Biological Survey Collection at Marshall University (WVBS 10600). Verified by Thomas K. Pauley. Represents the first county record for this species and extends the known range in West Virginia 50 km W (Green and Pauley 1987, Amphibians and Reptiles in West Virginia, Univ. Pittsburgh Press. xi + 241 pp.).

Submitted by **ALLAN J. NIEDERBERGER**, West Virginia Division of Natural Resources, Romney, West Virginia 26757, USA, and **MICHAEL E. SEIDEL**, Department of Biological Sciences, Marshall University, Huntington, West Virginia 25755, USA.

CLEMMYS MUHLENBERGII (Bog Turtle). USA: NORTH CAROLINA: CHEROKKE CO: 4.8 km E Andrews. May 1988. J. M. Bauman. North Carolina State Museum of Natural Sciences (NCSM A.N. 95-8-15; specimen maintained in live collection). New county record; extends range ca. 14 km WNW of nearest records in Macon County (Palmer and Braswell 1995, Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill. 412 pp.). GRAHAM CO: 11.3 km ESE Robbinsville. July 1996. M. Hopey. NCSM 45684 (shell). New county record. Extends range ca. 18 km NW of nearest records in Macon County (Palmer and Braswell 1995, Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill. 412 pp.). Both verified by William M. Palmer.

Submitted by **DENNIS W. HERMAN** and **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, P. O. Box 29555, Raleigh, North Carolina 27626-0555, USA.

TRACHEMYS GAIGEAE (Big Bend Slider). USA: TEXAS: BREWSTER CO: Rio Grande at mouth of Reagan Canyon. 20 April 1997. W. G. Degenhardt, J. R. Dixon, M. Dixon, and M. E. Seidel. University of New Mexico Museum of Southwestern Biology (MSB) 60768–70 and a living specimen to be deposited in the Texas Cooperative Wildlife Collection (TCWC, field no. JRD 33425). Verified by James N. Stuart. Extends range downstream in the Rio Grande 37 km (airline) from its previously known limit at Rio Grande Village (near Boquillas) Brewster County, Texas (Ernst 1992, Cat. Am. Amphib. Rept. 538:1–14). *Trachemys gaigeae* was also collected along intermediate sites at the mouth of Maravillas and Big Canyons, indicating a continuous distribution along this portion of the Rio Grande downstream from Big Bend National Park.

Submitted by **MICHAEL E. SEIDEL**, Department of Biological Sciences, Marshall University, Huntington, West Virginia 25755, USA, **WILLIAM G. DEGENHARDT**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA, and **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

SAURIA

CHAMAELEO CHAMAELEON (Common Chameleon). PORTUGAL: ALGARVE: Lagos. 22 July 1994 (37°05'N, 08°41'W). SPAIN: ANDALUCA: Ayamonte. 1 August 1994 (37°15'N, 07°26'W); Torremolinos. 8 May 1994 (36°38'N, 04°30'W); Almuñecar. 12 September 1994 (36°43'N, 03°40'W). All specimens collected DOR. Department of Animal Biology and Ecology, University of Granada (AL 940721, adult female; HU 940801, adult male: MA 940508, adult male; GR 940912, adult male). All verified by J. M. Pleguezuelos. These records represent a considerable range extension of the species in the Iberian Peninsula, either as a continuous invasion, or as an interrupted but efficient incursion. This suggests that the *C. chamaeleon* has great adaptive plasticity. Efforts should be made for the conservation of this species in Europe.

Submitted by **MANUEL BLASCO**, Department of Animal Biology, University of Extremadura, 06071 Badajoz, Spain, and **DIEGO GONZALEZ**, Guadiana School, P.O. Box 147, Ayamonte, Huelva, Spain.

EUMECES BREVIROSTRIS INDUBITUS (Mexican Shortnose Skink). MEXICO: MICHOACAN: 6.8 km WNW Charán, 2286 m. 12 November 1970. Fred G. Thompson. UF 45523. Verified by F. Wayne King. First confirmed record for the state (the previous record was based on *E. dugesii* fide Dixon 1969, Los Angeles Co. Mus. Nat. Hist. Contr. Sci. 168:12), and the only record for the subspecies between western Mexico (state) and Jalisco and Durango (Robinson 1979, Los Angeles Co. Mus. Nat. Hist. Contr. Sci. 319:11). The specimen is an adult conforming in all respects with the distinctive characteristics of the subspecies.

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA; **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 90309, USA.

EUMECES OCHOTERENAE (Guerreran Skink). MEXICO: OAXACA: San Vicente, Putla district. 1972. Thomas MacDougall. UCM 52640. Verified by Richard L. Holland. First record for the state of Oaxaca and a range extension of ca. 160 km ESE of the nearest records in central Guerrero (Dixon 1969, Los Angeles Co. Mus. Nat. Hist. Contr. Sci. 168:13, 19–20). No Notable differences are apparent in comparison with material from Guerrero, the only state of previous record.

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309, USA, and **FRANK VAN BREUKELEN**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: LOUISIANA: NATCHITOCHES PARISH: 31°44'6"N, 93°5'54"W, ca. 0.1 km NE Northwestern State University. 8 March 1997. John Ray. Northwestern State University Museum (NSU 5260). Verified by Kenneth Williams. First record for Natchitoches Parish (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.; Harold Dundee, personal comm. 22 January 1997.; David Good, personal comm. 24 January 1997).

Submitted by **JOHN RAY** and **BETSY COCHRAN**, NSU Box 3153, Natchitoches, Louisiana 71497, USA. E-mail: nsray2796@alpha.nsula.edu.

OPHISAURUS COMPRESSUS (Island Glass Lizard). USA: GEORGIA: CAMDEN CO: Cumberland Island , interdune area east of Cedar Dock Road. 17 February 1993. C. Robert Shoop and Carol Ruckdeschel. USNM 511177. Verified by R. I. Crombie. In 1986, we noted the unconfirmed presence of several species listed by other authors as potential residents of Cumberland Island, Georgia (Herpetol. Rev. 17:51). This specimen establishes the presence of this species on the north end of the island. Another specimen, subsequently found dead in the same habitat, has been deposited in the Cumberland Island Museum. Although present in surrounding Georgia counties, these lizards represent the first Camden County records (Williamson and Moulis 1994, Distribution of Amphibians and Reptiles on Georgia. Savannah Sci. Mus. Spec. Publ. No. 3).

Submitted by **C. ROBERT SHOOP**, Department of Biological Sciences, University of Rhode Island, Kingston, Rhode Island 02881-0816, USA, and **C. RUCKDESCHEL**, Cumberland Island Museum, P.O. Box 796, St. Marys, Georgia 31558-0796, USA.

PRIONODACTYLUS ARGULUS. BRAZIL: ACRE: Rio Branco, Centro Experimental da Universidade Federal do Acre, Km 29 da AC-010 (10°03'S, 67°51'W). 17 March 1993. M. Henzl and L. Ford. Museu Paraense Emilio Goeldi (MPEG 16774). Verified by R. N. Yuki. First state record (Avila-Pires 1995, Zool. Verh. Leiden 299:458).

Submitted by **ALMIRA CLAUDIA MARINHO LIMA**, Departamento de Zoologia, Museu Paraense Emilio Goeldi, Caixa Postal 399, CEP 66.040-170, Belem, Para, Brazil. E-mail: claudia@museu-goeldi.br .

PRIONODACTYLUS EIGENMANNI. BRAZIL: ACRE: Rio Branco, Centro Experimental da Universidade Federal do Acre, km 29 da AC-010 (10°03'S, 67°51'W). 10 March 1993, Museu Paraense Emilio Goeldi (MPEG 16767–16768); 11 March 1993

(MPEG16770–16771); 17 March 1993 (MPEG 16773). All collected by M. Henzl and L. Ford. Verified by R. N. Yuki. First state records (Avila-Pires 1995, Zool. Verh. Leiden 299:468).

Submitted by **ALMIRA CLAUDIA MARINHO LIMA**, Departamento de Zoologia, Museu Paraense Emilio Goeldi, Caixa Postal 399, CEP 66.040-170, Belem, Para, Brasil. E-mail: claudia@museu-goeldi.br.

SAUROMALUS OBESUS (Chuckwalla). USA: NEVADA: ESMERALDA CO: on isolated rocky outcrop near Bonnie Claire Flat, 1260 m elev. (37°08.845'N, 117°10.925'W). 16 May 1995. Paul C. Ustach. PCU Field No. 188. New county record and northwest range extension. LINCOLN CO: Hell's Half Acre, Hiko Range, 1400 m elev. 27 April 1995. Paul C. Ustach. PCU Field No. 181. Northern range extension. Both verified by Edmund D. Brodie, Jr. Specimens eventually will be deposited at the University of Texas at Arlington.

Submitted by **PAUL C. USTACH**, Department of Biology, Utah State University, Logan, Utah 84322-5305, USA.

SCELOPORUS HORRIDUS OLIGOPORUS (Mexican Horrible Spiny Lizard). MEXICO: NAYARIT: 3.9 km NW Chapalilla, 1036 m. 21 May 1966. Fred G. Thompson. UF 34831. Verified by F. Wayne King. An adult male 95 mm SVL with 2-2 femoral pores and strong abdominal and gular semeions. First record for the state (Smith 1939, Zool. Ser. Field Mus. Nat. Hist. 26:99, 106–108), where the only representatives of the species previously recorded are *S. h. albiventris*, which apparently is replaced in the western, more elevated part of the state, by *S. h. oligoporus*.

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainsville, Florida 32611, USA, **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309, USA.

SCELOPORUS PARVUS SCUTULATUS (Southern Bluebelly Lizard). MEXICO: ZACATECAS: 25.3 km SW San Tiburcio, 2316 m. 7 August 1966. Fred G. Thompson. UF 34975. Verified by F. Wayne King. First record of the species for the state, supplementing the northernmost record for the subspecies 48 km N Matehuala, San Luis Postosí (Smith 1939, Zool. Ser. Field Mus. Nat. Hist. 26:255–6, 284). With 22 nape rows, 69 dorsals, anterior section of frontal not divided.

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309, USA; and **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainsville, Florida 32611, USA.

SCELOPORUS UNDULATUS ELONGATUS (Nothern Plateau Lizard). USA: COLORADO: ROUTT CO: 1 km W Pagoda. 29 June 1997. Frank van Breukelen. UCM 58772. Verified by Richard L. Holland. First county record (Livo et al. 1996, Herpetological microbiogeography of Colorado II: documented and potential county records. Publ. Colorado Herpetol. Soc. 22 pp.) and a northeastern range extension of 42 km (airline) from the Yampa River south of Lay on the bluffs of the Williams Fork River.

Submitted by **FRANK VAN BREUKELEN,** Department of EPO Biology, University of Colorado, Boulder, Colorado 90309, USA, **JAN ROTH,** Sundance Museum, 417 Breeze Street, Craig, Colorado 81625, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309, USA and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado Museum, Boulder, Colorado 80309, USA.

SCINCELLA LATERALIS (Ground Skink). MEXICO: DURANGO: ca. 14.5 km SSW Picardias, 1341 m (confirmed by field notes; 1400 ft. on tags in error). 28 December 1969. Fred G. Thompson. UF 105868–869. Verified by F. Wayne King. These represent an apparently isolated population ca. 7 km W of the Coahuila border, ca. 33 km (airline) SSW Torreón, Coahuila (Schmidt and Owens 1944, Zool. Ser. FMNH 29:107) at much the same altitude (1320 m). No notable differences were detected from U.S. material.

Submitted by **HOBART M. SMITH**, Department of EPO Biology and Museum, University of Colorado, Boulder, Colorado 80309-0334, USA, **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA.

SERPENTES

BOTHROPS NEUWIEDI (Neuwied's Lancehead). BRAZIL: AMAZONAS: HUMAITÁ: Savanna Region. G. R. Colli. Departamento de Zoologia, Museu Paraense Emílio Goeldi (MPEG 18951, 17 October 1991, MPEG 18954–55, 30 October 1991). Verified by G. Puorto. New county record (Campbell and Lamar 1989, The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. 425 pp.). The Humaitá Region is an area between the main distribution of this snake and an isolated population (Campbell and Lamar, *op. cit.*).

Submitted by **RUBENS NOBUO YUKI**, Departamento de Zoologia, Museu Paraense Emílio Goeldi, Caixa Postal 399, Belém, Pará, Brazil CEP 66017-970.

CHIRONIUS FLAVOLINEATUS. BRAZIL: AMAZONAS: HUMAITÁ: Escola Agrotécnica de Humaitá (7°31'S, 63°02'W). 9 November 1991. Guarino R. Colli. Coleção Herpatológica da Universidade de Brasília (CHUNB 00217–18); AMAPÁ: FERREIRA GOMES: Fazenda Teinmoso (1°02'06"N, 51°10'02"), 17 April 1997. Guarino R. Colli and Ayrton K. Péres Jr. CHUNB 00219. All verified by Nelson Jorge da Silva Jr. First records for the states of Amapá and Amazonas; both in Amazonian Savanna habitats; extends range ca. 250 km NW from previous northern limit of distribution (Ilha de Marajó; Dixon et al. 1993, Monographie XIII, Museo Regionale di Scienze Naturali, Torino. 279 pp.) and ca. 800 km N of western limit of distribution (central Bolivia, ibid.).

Submitted by **GUARINO R. COLLI** and **AYRTON K. PÉRES JR.**, Departamento de Zoologia, Universidade de Brasília, 70910-900, Brasília, Distrito Federal, Brazil. E-mail (GRC): grcolli@guarany.cpd.unb.br.

CLELIA RUSTICA (Mussurana) ARGENTINA: MENDOZA: ca. 20 km SSE of Malargüe city (35°28'S, 69°35'W). 2 December 1992. Gustavo Marino. Herpetological collection of PROBBAS, Consejo Nacional de Investigaciones Científicas y Técnicas, Corrientes, Argentina (CFA 226, female). Verified by Gustavo Couturier. First province record; extends range ca. 440 km air line W from nearest known locality in Villa Valeria, Córdoba Province (Scrocchi and Viñas 1990, Boll. Mus. Reg. Sci. Nat. Torino 8(2):487–499).

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). USA: TEXAS: McMULLEN Co: DOR at jct FM 624 and Tex. Rt. 16 on Tex. Rt. 16. 3 May 1997. Travis J. LaDuc and Christopher R. Harrison. TNHC 55958. Verified by David C. Cannatella. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **TRAVIS J. LaDUC**, Department of Zoology, The University of Texas at Austin, Austin, Texas 78712-1064, USA and **CHRISTOPHER R. HARRISON**, Department of Wildlife and Fisheries Sciences, Texas A & M University, College Station, Texas 77843, USA.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). USA: WYOMING: SWEETWATER Co: 3.2 km W of Rt. 430 on road to Hiawatha. 27 June 1992. David Chiszar and Hobart M. Smith. UCM 57059. Verified by Alan de Queiroz. County record (Baxter and Stone 1980, Amphibians & Reptiles of Wyoming. Publ. Wyoming Game and Fish Department). Previously *C. v. concolor* was the only race of this species known from Sweetwater County.

Submitted by **KYLE G. ASHTON** and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309, USA.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: ARIZONA: MOHAVE Co: 1 mi S of Oatman on U.S. Rt. 66. 29 April 1997. Paul C. Ustach and Daniel H. Foley. DHF Field No. 111. Verified by Edmund D. Brodie, Jr. Found dead on road. Specimen eventually will be deposited at the University of Texas at Arlington.

Submitted by **PAUL C. USTACH**, Department of Biology, Utah State University, Logan, Utah 84322-5305, USA.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: NEVADA: CLARK Co: Newberry Mountains, Hiko Spring, 630 m elev. (37°41'35"N, 85°22'33"W). 12 April 1995. Paul C. Ustach. PCU Photograph 005. Verified by Edmund D. Brodie, Jr. Individual was found stretched out in the middle of a dry wash about 400 m from the surface flow of Hiko Spring. Specimen eventually will be deposited at the University of Texas at Arlington.

Submitted by **PAUL C. USTACH**, Department of Biology, Utah State University, Logan, Utah 84322-5305, USA.

DIADOPHIS PUNCTATUS REGALIS (Regal Ringneck Snake). USA: TEXAS: EDWARDS Co: DOR, 10.2 road mi W Rocksprings on Tex. Rt. 55. 10 May 1997. Travis J. LaDuc. UTEP 17162. Verified by Carl S. Lieb. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.); size of specimen (335 SVL + 60 mm tail length) suggests *D. p. regalis* instead of *D. p. arnyi.*

Submitted by **TRAVIS J. LaDUC**, Department of Zoology, The University of Texas at Austin, Austin, Texas 78712-1064, USA.

FARANCIA ERYTROGRAMMA ERYTROGRAMMA (Rainbow Snake). USA: FLORIDA: BAKER Co: south prong of the St. Mary's River at U. S. Rt. 90 and State Road 10 bridge, between Macclenny and Glen St. Mary. 16 June 1988. William H. Kern. Florida Museum of Natural History (UF 72535). Verified by F. Wayne King. County record; fills gap of ca. 70 mi between Duval and Columbia counties. NASSAU Co: 2 mi E of U. S. Rt. 17 on S shore of St. Mary's River, White Oak Plantation. 13 May 1997. Patrick J. Ryder. UF 106014. Verified by F. Wayne King. County record; fills a gap of ca. 70 mi between Glynn County (Georgia) and Duval County (Florida). First two records for the St. Mary's River drainage (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Windward Publ., Miami. 176 pp.; Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Pub. No. 2. 418 pp.).

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA.

LAMPROPELTIS TRIANGULUM TRIANGULUM (Eastern Milk Snake). USA: ILLINOIS: KANE Co: 6 mi W Geneva. 16 May 1974. SE Sec. 31, T40N, R8E. Doug Brown. Museum of Northern Illinois University (HDW-NIU 1347). Verified by Jerry Stubbs. Specimen found crossing Rt. 38. Documents county record of Necker (1939, Chicago Acad. Sci. Bull. 6[1]:1–10) for which no voucher specimen is known.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

LYSTROPHIS MATOGROSSENSIS (South American Hognose Snake). BOLIVIA: SANTA CRUZ: SANDOVAL: Estancia Cascavel (16°38'S, 57°29'W). 12 September 1994. Julio R. Contreras. Herpetological collection of PROBBAS, Consejo Nacional de Investigaciones Científicas y Técnicas, Corrientes, Argentina (CFA 725, male). Verified by Gustavo J. Scrocchi. First record for Bolivia; extends range ca. 100 km air line W from westernmost known locality in Caceres, Brazil. The species was known only from Mato Grosso and Mato Grosso do Sul states, Brazil (Scrocchi and Cruz 1993, Papeis Avulsos Zool. 38:171–186).

Submitted by **ALEJANDRO R. GIRAUDO**, Becario de CONICET, Instituto Nacional de Limnología, José Macia 1933, 3016, Santo Tomé, Santa Fe, Argentina.

NERODIA SIPEDON PLEURALIS (Midland Water Snake). USA: TENNESSEE: SHELBY Co: Germantown, SE margin of pond adjacent to Wolf River, 0.2 km E of Germantown Parkway, 35°07'N, 89°48'W. 9 May 1997. MSUMZ Color Slide R-1133. Verified by William H. N. Gutzke. Extends species range to southwestern Tennessee (Morris, 1987, Systematics and Distribution of the Northern Water Snake, *Nerodia sipedon* [Linnaeus], with Comparisons to *Nerodia fasciata* [Linnaeus], Ph.D. Dissertation, Southern Illinois University, Carbondale). Range extension supported by Hassell's records (1961, A Herpetological Survey of Shelby Forest State Park. Masters Thesis, University of Memphis) in Shelby County and Norton's records (1971, The Herpetofauna of Hardeman County, Tennessee. Masters Thesis, University of Memphis) in Hardeman County. Logan's records (1969, A Survey of the Herpetofauna of De Soto County, Mississippi. Masters Thesis, University of Memphis) in DeSoto County suggest that the species also may occur in extreme northwestern Mississippi.

Submitted by **STEPHEN J. MULLIN**, Department of Biology, University of Memphis, Memphis, Tennessee 38152, USA, and **JAMES T. EUBANKS**, 4930 Verne Memphis, Tennessee 38117, USA.

OXYRHOPUS RHOMBIFER INAEQUIFASCIATUS (Falsa Coral, False Coral Snake). ARGENTINA: CORRIENTES: Corrientes: Captial. (27°35'S, 58°45'W). 4 December 1996. Laura Rey. Colección Herpetológica de la Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC- 05156). Verified by Gustavo Scrocchi. First province record (Cei 1993, Monograf. XIX . Mus. Reg. Sci. Nat. Torino).

Submitted by **LAURA R. REY**, Departamento de Herpetología, CEPSAN, Avenida Costanera 255 (3400) Corrientes, Argentina, and **MARIA LUISA LIONS**, Cátedra de Anatomía Comparada, Facultad de Ciencias Exactas y Naturales y Agrimensura, UNNE, 9 de Julio 1449, (3400) Corrientes, Argentina.

PSEUSTES SULPHUREUS. BRAZIL: SÃO PAULO: PARANAPIACABA (23°48'S, 46°03'W). August 1974. Collector unknown. Museo de Zoologi da Universidade de São Paulo (MZUSP 5622). Verified by Paulo E. Vanzolini. Species normally is found in Amazonian and Atlantic Forest. First state record; the southern limit of its range was reported previously as Maricá, RJ (22°57'S, 42°49'W) (Peters and Orejas-Miranda 1970, Bull. U.S. Nat. Mus. 297:259).

Submitted by **OTAVIO A. V. MARQUES** and **MYRIAM E. CALLEFFO**, Laboratório de Herpetologia, Instituto Butantan. Avenida Vital Brasil, 1500, CEP 05503-900, São Paulo, São Paulo, Brazil.

RHINOTYPHLOPS PRAEOCULARIS. NIGERIA: GONGOLA: Adamawa: Yola, 09°12'N, 12°29'E, ca. 500 m. Zoological Museum, University of Copenhagen (ZMUC R52197). Verified by V. Wallach. A rare species; only 12 specimens known, as follows: S Congo (Brazzaville, MNHN 1986.730), SW Zaire (vic. of Kisangani, USNM 20799, LACM 49690-93), NE Angola (Dundo, MD 5252, 5959, 5932, 5935, 5938), and "West Africa" (unknown locality, FMNH 75088). Adult female, 24 scale rows, 545 middorsals. First record for Nigeria and range extension of ca. 1500 (airline) km N of Brazzaville (Roux-Esteve 1974, Mem. Mus. Natn. Hist. Nat. 87A:1–313).

Submitted by **JENS B. RASMUSSEN**, Zoological Museum, University of Copenhagen, Universitetsparken 15, DK-2100 Copenhagen Ø, Denmark.

TANTILLA CALAMARINA (Pacific Coast Centipede Snake). MEXICO: PUEBLA: 12.5 km SE Izucar de Matamoros, 1475 m (18°31'16"N, 98°24'59"W), on a microwave tower hill under a limestone boulder in xeric scrub thicket. 21 February 1992. Fred G. Thompson. UF 102793. Verified by F. Wayne King. First verified and credible record for the state (Wilson 1988, Cat. Am. Amph. Rept. 433:1–2). A record for Teziutlan, Puebla (Cope 1885, Proc. Am. Philos. Soc. 22:381), is neither verifiable (specimen lost) nor credible (geographically inconsistent), and was for those reasons rejected by Wilson (*loc. cit.*).

Submitted by **HOBART M. SMITH,** Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309, USA, and **DAVID L. Field work in northwestern Argentina during the austral summer of 1995 resulted in significant new records for five species of *Liolaemus*—three of them recently described members of the *darwinii* complex—and for one species of *Pristidactylus*. The identities of all specimens were verified by Fernando Lobo. Voucher specimens have been deposited at San Diego State University (SDSU) or the Fundación Miguel Lillo (FML). Latitude, longitude, and elevation were determined with a Scout™ global-positioning device (Trimble Navigation Systems, Sunnyvale, California, USA).

Tropiduridae

Liolaemus cuyanus (NCN). LA RIOJA PROVINCE: Dpt. Gral. Lavalle, 42 km SW of Villa Unión on Ruta Nac. 40 (29°30'59"S, 68°30'51"W, 1050 m). 19 January 1995. SDSU 3435. An adult female was found basking on a rock along the road. The previous westernmost records are from 67°41'51"W in southern San Juan Province, and 67°38'0"W in southwestern Catamarca Province. This record constitutes a range extension of ca. 140 km west for the species and provides support for Cei's (1993) contention that this species is distributed throughout most of the non-Andean regions of this province. The substratum was one of loose sand with smooth stones and small boulders, but lacking dunes or extensive areas of open sand.

Liolaemus koslowskyi (NCN). LA RIOJA PROVINCE: Dpt. Gral. La Madrid, 10.8 km N of Villa Castelli on Ruta Prov. 26 (28°55'50"S, 68°11'11"W, 1410 m). 18 January 1995. SDSU 3597. This is the second record for this species from the valley of the Río Vinchina; extends the known range ca. 50 km north of the previously reported westernmost record (Etheridge 1993). Of greater significance, however, is the discovery of *Liolaemus olongasta* to the north (see below).

Liolaemus laurenti (NCN). LA RIOJA PROVINCE: Dpt. Independencia, sand dunes 51 km W of Patquia on Ruta Prov.

150 (30°12'21"S, 67°20'27"W, 900 m). 8 February 1995. SDSU 3475–76. Extends the range about 35 km east of Baldecitos, San Juan Province; SAN JUAN PROVINCE: Dpt. Caucete, sand dunes 4 km W of Bermejo on Ruta Nac. 210 (31°36'05"S, 67°41'51"W, 690 m). 9 February 1995. FML 3452(6). This locality extends the range ca. 260 km south of Baldecitos, which was previously the most southerly record (Etheridge 1992). All records for this species are from sand flats or dunes. The absence of records from the intervening region may be due to the fact that the only road connecting the two localities passes to the east of the Sierra del Valle Fértil and the Sierra de la Huerta where sandy habitats are absent. *Liolaemus laurenti* may occur on the scattered sand dunes of the great valley of the Río Bermejo that lies west of these ranges, but has eluded detection because there are no roads to access this area.

Liolaemus olongasta (NCN). LA RIOJA PROVINCE: Dpt. Vinchina, sand dunes just W of the jct. of Ruta Prov. 16 and road spur to Bajo Jagüé (28°39'26"S, 68°20'11"W, 1790 m). 18 January 1995. FML 3454 and SDSU 3544–47. This site is ca. 135 km north of the type locality, which was previously the most northerly record for this species (Etheridge 1993). Individuals were observed only on sand dunes. The dunes were surrounded by rocky ground where no other *Liolaemus* were seen. Etheridge (1993) noted the existence of a small series of *L. olongasta* recorded from "Jagzuél, al pie de la Cordillera," but the province was not specified. Given this new record, it is likely that the previously ambiguous locality may refer to either Alto Jagüé or Bajo Jagüé. The dunes are located near an upper tributary of the Rio Vinchina, ca. 35 km north of the most northerly record in this valley for *L. koslowskyi* (reported above). Thus, the distribution of *L. koslowskyi* appears to be interposed between that of *L. olongasta* on the dunes of Bajo Jagli in the north, and on the sand flats of Talampaya south of Villa Unión. Several of the females we collected in this region were gravid and exhibited bright yellow coloration along their posterior jaws. This suggests the presence of gravid female coloration in *L. olongasta;* SAN JUAN PROVINCE: Dpt. Jáchal, gravel flats 28.1 km E of Rodeo on Ruta Prov. 150 (30°12'40"S, 68°53'07"W, 1350 m). 19 January 1995. SDSU 3613–16. While specimens from this locality (between Rodeo and San José de Jáchal) do not represent a range extension, they are noteworthy because of their color pattern and the substratum upon which they were found. Although Etheridge (1993) had noted records for *L. olongasta* from San Juan Province, he had only observed this species on the Talampaya sand flats of western La Rioja Province. The dorsal color pattern exhibited by *L. olongasta* that live on sand is remarkably cryptic [e.g., individuals from the dunes near Bajo Jagüé and the Talampaya flats (Etheridge 1993, Pl. 2.4–5)]. In contrast, males from the gravel flats east of Rodeo have a darker, bolder pattern, with bright yellow dorsolateral stripes and numerous iridescent blue scales; SAN JUAN PROVINCE: Dpt. Jáchal, rocky flats 54 km NNE San José de Jáchal on Ruta Prov. 40 (29°57'24"S, 68°29'25"W, 1050 m). 21 January 1995. SDSU 3515. This record fills in a large gap between the type locality and the locality reported by Etheridge (1993) at 3 km northwest of San José de Jáchal; SAN JUAN PROVINCE: Dpt. Iglesia, gravel flats just N of Tocota on Ruta Nac. 141 (30°41'02"S, 69°26'38"W, 2550 m). 19 January 1995. Two hatchlings (26 mm SVL) that were collected, but subsequently lost, are apparently referable to this species and, if so, represent a range extension of ca. 70 km SSW of Rodeo.

Liolaemus pseudoanomalus (NCN). CATAMARCA PROVINCE: Dpt. Tinogasta, rocky flats 12.8 km S of Fiambalá on Ruta Prov. 45 (27°47'7"S, 67°39'40"W; 1470 m). 16 January 1995. SDSU 3540. This record extends the range reported for this species by Cei (1993) ca. 160 km northwestward into the valley of the Rio Abaucán. Etheridge (1993) noted that this species occurs here syntopically with *Liolaemus abaucan,* based on specimens from 8.2 and 8.8 km north of Fiambalá (SDSU 1310–11).

Polychrotidae

Pristidactylus scapulatus (NCN). SAN JUAN PROVINCE: Dpt. Iglesia, at the base of a small hill on rocky ground about 0.5 km S of Tocota, just E of Ruta Prov. 412 (30°41'2"S, 69°26'38"W, 2550 m). 20 January 1995. SDSU 3448. This locality is about half way between previous records for this species from the Cordillera de San Guillermo (3500 m) in extreme northwestern San Juan Province (Cei et al. 1983), and the Sierra de Uspallata (2520–2768 m) in extreme northwestern Mendoza Province (Cei and Roig 1976)—a distance of 400 km. The individual was an adult male that retreated into a rodent burrow (probably *Ctenomys* sp.) upon approach. In our experience, *P. scapulatus* is typically found in association with large boulders, but no such refugia were available in this area.

Acknowledgments.—We thank E. Lavilla, F. Lobo, J. C. Moreta, and S. Torres for invaluable field assistance. We are grateful to R. Laurent, M. Halloy, and R. Montero and their families for providing logistic support while in Tucumán. Lizards were collected under the authority of the Instituto de Herpetología, Fundación Miguel Lillo, Tucumán. Partial funding was provided to the junior author by the American Society of Ichthyologists and Herpetologists, the Chicago and San Diego Herpetological Societies, the Explorers Club, the Graduate Degree Program in Ecology at Colorado State University, and by generous contributions from the Burdett, Cousins, and Deaton families. This note was written while the junior author was supported by a Porter Fellowship from the American Physiological Society.

182 Camellia Way, Midway, Georgia 31320, USA

St. Catherines Island, Liberty County, Georgia (USA), is a 56 km^2 (5,666 ha) barrier island situated 80 km south of Savannah, between Ossabaw and Sapelo islands. St. Catherines Island has been inhabited by humans for more than 4500 years (Larsen 1982) and has had an extensive cultural history (Thomas et al. 1978). As earlier studies of barrier island amphibians and reptiles (see Gibbons and Coker 1978) have shown, St. Catherines likewise has a depauperate herpetofauna (Zweifel and Cole 1974) compared with that occurring on the mainland. Certainly, Native American exploitation, followed by Spanish settlement, subsequent plantation agricultural activities and lumbering, and cattle and swine ranching, coupled with violent weather phenomena, impacted post-Pleistocene plant and animal colonizers and helped shape today's herpetofaunal elements.

Since 1970, the St. Catherines Island herpetofauna has been well scrutinized by zoologists from the American Museum of Natural History, New York University, Wildlife Conservation Society, Georgia Southern University, University of the South, Georgia Department of Natural Resources, and scores of visiting biologists from other institutions. Some twelve species of snakes are known from St. Catherines Island: *Nerodia fasciata, Thamnophis sirtalis, T. sauritus, Opheodrys aestivus, Coluber constrictor, Elaphe obsoleta, E. guttata, Cemophora coccinea, Lampropeltis getula, Agkistrodon piscivorus, Crotalus horridus,* and *C. adamanteus.* There have been no confirmed additions to Zweifel and Cole's (1974) list. Except for the natricines and *Coluber* and *Elaphe*, other species were not commonly seen before the mid-1980s. Large populations of feral hogs and cattle (both introduced in the 1930s) dramatically damaged and opened the understory and likely negatively impacted most resident snake populations. Since removal of the cattle (1975–1983) and suppression of the feral hogs (<100 adults 12/96), the understory has recovered, and snake observations have become more frequent.

In 1985, St. Catherines Island was evaluated as a potential release site for the endangered *Drymarchon couperi* by Dan Speake, Team Leader, Eastern Indigo Snake Recovery Plan. It was judged that suitable habitat existed and a plan was advanced to introduce the gopher tortoise (*Gopherus polyphemus*) to hold dune and savanna area on the north end of the island to enhance the "indigo snake" habitat. *Gopherus* has been introduced there, but no *Drymarchon* have been liberated.

On the basis of a 1983 photograph, Couper et al. (1996) reported a "confirmed" record of *Drymarchon couperi* from St. Catherines Island as the first such event for any barrier island. The photo was reported (to BW) to have been taken in the immediate vicinity of the student housing facilities during the senior author's visit to the island that year. One of us (RHH) recalls the photo event. Based upon examination of the developed photograph, habitat, and behavior of the snake in question, RHH in 1983 identified the snake as a racer (*Coluber constrictor*). Couper commented (to BW) that only one photograph (UCM Color Slide 114) was taken and the author provided the voucher slide to the University of Colorado Museum. UCM Color Slide 114 was the same photograph seen years earlier by RHH and clearly depicts a *Coluber constrictor*.

Many thousands of man hours have been devoted to the exploration of the fauna and flora of St. Catherines Island. Consequently, the herpetofauna is well known. It does not include the normally conspicuous and largest non-venomous snake species (*Drymarchon couperi*) in North America.

Acknowledgments.—Thanks are extended to David Chiszar for providing a duplicate copy of the voucher slide.

Status of Possible Disjunct Populations of the Southern Toad, *Bufo terrestris*, in the Piedmont and Blue Ridge of Georgia

JOSHUA LAERM
Museum of Natural History, University of Georgia
Athens, Georgia 30602, USA
e-mail: laerm@museum.nhm.uga.edu

and

ARTHUR S. HOPKINS, JR.
Department of Geography, University of Georgia
Athens, Georgia 30602, USA

The status of disjunct populations of the southern toad, *Bufo terrestris* (Bonnaterre), in the Upper Piedmont and Blue Ridge physiographic provinces of South Carolina and Georgia, USA, is confused. Wright and Wright (1949, Handbook of Frogs and Toads of the United States and Canada. Comstock Publ. Assoc., Ithaca, New York. p. 199) questioned "are the isolated records (one, western South Carolina; one, northern Georgia)...misidentification or intermediates?" Martof et al. (1980, Amphibians and Reptiles of the Carolinas and Virginia. Univ. North Carolina Press, Chapel Hill. 264 pp.) do not indicate disjunct populations of *B. terrestris* in the Upper Piedmont or Blue Ridge of South Carolina. However, Blem (1979, Cat. Amer. Amph. Rept. 223.1–223.4.) and Conant and Collins (1991, Peterson Field Guide to Amphibians and Reptiles of Eastern and Central North America. Third Ed. Houghton Mifflin, Boston, Massachusetts. 450 pp.) correctly map disjunct records. Ostensibly, these are based on previously published records of Pickens (1927, Copeia 165:106–110), Burt (1938,

Trans. Kansas Acad. Sci. 41:331–366), and Chamberlain (1939, Charleston Mus. Leafl. 12:1–38), as well as museum records (United States National Museum and Charleston Museum) from portions of Anderson, Greenville, and Pickens counties. These include records from both Upper Piedmont and Blue Ridge physiographic provinces.

Insofar as we can determine, Wright and Wright (*op. cit.*) are the only authorities to have commented on the possibility of disjunct populations occurring in adjacent regions of Georgia. Williamson and Moulis (1994, Savannah Sci. Mus. Spec. Publ. 3:1–712) include in their locality data (but do not map) a single record of *Bufo terrestris* from Rabun County, Georgia (10 mi. NE Dillard) based on a University of Georgia Museum of Natural History record. The specimen had been cataloged and correctly identified as a *B. americanus*. Additionally, we searched museums in the United States with holdings of *B. terrestris* from Georgia. We examined six *B. terrestris* from the Blue Ridge in Rabun County (UMMZ 45876-45881). Our attribution of these specimens to *B. americanus* is confirmed by Alan Resetar. We also examined a *B. terrestris* (UMMZ 91963) from the Upper Piedmont of Lumpkin County, which is referable to *B. woodhousii fowleri* (confirmed by G. Schneider; see also Williamson and Moulis 1994.). We conclude that while extralimital populations of *B. terrestris* appear well established in the Upper Piedmont and Blue Ridge of South Carolina, there is no evidence of their occurrence in adjacent regions of Georgia. Populations in Georgia are restricted approximately to the Fall Line south as indicated in Conant and Collins (*op. cit.*) and Williamson and Moulis (*op. cit.*).

New County Records of Amphibians and Reptiles from Georgia

GREGORY B. LACY
Department of Biological and Environmental Sciences
Georgia College and State University, Milledgeville, Georgia 31061, USA
e-mail: glacy@peachnet.campus.mci.net

Distribution records of the amphibians and reptiles of Georgia have been documented by Williamson and Moulis (1994) and additional records have been added by Laerm et al. (1996). However, distribution records for several Georgia counties are lacking, especially in the central part of the state. The Georgia College and State University Herpetological Collections hold numerous species that are the first records for counties. Identification of all specimens were verified by Dennis Parmley (unless otherwise noted), and are deposited in the GCSU comparative skeletal collection unless otherwise noted.

Desmognathus auriculatus (Southern Dusky Salamander). Hancock Co: 19.3 km S of Sparta. 23 April 1995. Dennis Maddox. GCSU 4238. Extends range 27 km north of nearest record in Wilkinson County.

Eurycea longicauda guttolineata (Three-lined Salamander). Spalding Co: no other data. 15 April 1990. Collector unknown. GCSU 2408.

Plethodon glutinosus (Northern Slimy Salamander). Jasper Co: 8.1 km SE of Monticello. 8 May 1991. Barry Hooper. GCSU 3630.

Bufo americanus (American Toad). Baldwin Co: Ivey-Weaver Road, 1.3 km E of North Jefferson Street, Milledgeville. 9 April 1991. D. Peck. GCSU 3612. Extends range southeast one county from Putnam and Jones counties.

Rana sphenocephala utricularius (Southern Leopard Frog). Baldwin Co: Lake Laurel Road, 6 km NE Milledgeville. 28 March 1991. Dennis Parmley. Verified by D. Walker. GCSU 3615. Completes county sequence in central Georgia.

Eumeces fasciatus (Five-lined Skink). Baldwin Co: Ivey-Weaver Road, 1.3 km E of North Jefferson Street, Milledgeville. 16 September 1992. David Peck. GCSU 3565. Fayette Co: Peachtree City. 23 March 1990. Dennis Parmley. Verified by D. Walker. GCSU 3701.

Eumeces inexpectatus (Southeastern Five-lined Skink). Baldwin Co: Ivey-Weaver Road, 1.3 km E of North Jefferson Street, Milledgeville. 27 April 1990. Vertebrate Zoology class. GCSU 2338.

Eumeces laticeps (Broadhead Skink). Baldwin Co: Ivey-Weaver Road, 1.3 km E of North Jefferson Street, Milledgeville. 10 April 1991. D. Peck. GCSU 3628.

Sceloporus undulatus undulatus (Southern Fence Lizard). Upson Co: 4.5 km NE of Rock. 11 April 1991. Collector unknown. GCSU 3637. Fayette Co: Peachtree City. 23 March 1990. Dennis Parmley. Verified by D. Walker. GCSU 3664.

Elaphe obsoleta spiloides (Gray Rat Snake). Seminole Co: 24.2 km S of Dresser, Lake Seminole. 15 July 1990. Dennis Parmley. Verified by D. Walker. GCSU 3916. Fills distribution gap in southwestern Georgia between Early, Miller, and Decatur counties.

Farancia abacura abacura (Eastern Mud Snake). Bibb Co: I-75, 2.6 km E jct. I-16 and I-75. 25 September 1994. G. B. Lacy. DOR. GCSU 4002. Extends range ca. 29 km west from Wilkinson County.

Farancia erytrogramma erytrogramma (Rainbow Snake). Seminole Co: 24 km S of Dresser, Lake Seminole. 12 July 1990. Dennis Parmley. Verified by D. Walker. GCSU 2378. Nearest Georgia record is ca. 80 km to the northeast.

Lampropeltis getula getula (Eastern Kingsnake). Baldwin Co: Ivey-Weaver Road, 1.3 km E of North Jefferson Street, Milledgeville. 3 October 1996. Gabe Gaddis. Juvenile. Photo GCSU CP0001. Completes county sequence in central Georgia.

Masticophis flagellum flagellum (Eastern Coachwhip). Baldwin Co: Blandy Hills Road, NW Milledgeville. 19 August 1992. Dennis Parmley. Verified by D. Walker. GCSU 3705.

Nerodia erythrogaster erythrogaster (Redbelly Water Snake). Baldwin Co: 6.4 km W Milledgeville. Collector unknown. 1 May 1989. GCSU 2175. Jasper Co: 6.4 km SE Monticello. 14 April 1991. Barry Hooper. GCSU 2175.

Nerodia taxispilota (Brown Water Snake). Baldwin Co: Lake Laurel, 3.4 km N Lake Laurel Road and Ga. Rt. 22. 3 June 1991. Collector unknown. GCSU 3569. Putnam Co: Rt. 441 at Lake Sinclair. 15 April 1990. Al Mead. GCSU 2394. Warren Co: 19.8 km S Warrenton. 17 October 1993. Collector unknown. GCSU 3781.

Opheodrys aestivus (Rough Green Snake). Fayette Co: Peachtree City. 3 September 1989. DOR. Dennis Parmley. Verified by D. Walker. GCSU 2302. Putnam Co: no other data. 8 October 1989. Collector unknown. GCSU 2296.

Werner Himstedt has produced a long-needed, thoughtful, meticulous, and reasonably thorough and current overview of the information available about the indubitably most interesting (in my clearly unbiased opinion) but least well known amphibians, the caecilians. Himstedt wisely chose not to attempt to be all-inclusive, but presents considerable background information about caecilians while emphasizing his own work on the physiology, morphology, behavior and ecology of *Ichthyophis* in Thailand. The book, written in German, presents a scholarly and well chosen body of information, appropriate to all students of the biology of amphibians, and at the same time it is written in a manner that is accessible to the interested amateur keeper-and-observer of caecilians. The illustrations are excellent, many original and many re-drawn by Himstedt for clarity, and are large enough to be interpreted easily. A color plate illustrating six species in three families is of special interest.

The book includes eleven major sections, an extensive list of references, and an index. The introduction presents caecilians in a general context, then discusses early research on the systematics and biology of caecilians, including comments on the derivation of the name of the order. Special tribute is given to the pioneering work of the Sarasins, whose work published more than one hundred years ago remains the most comprehensive study of any species of caecilian. The second chapter on the ancestry of caecilians is a general view of the relationships of caecilians to other amphibians. Its emphasis on the impressions of Romer and Parsons and of Starck predominates (largely because of the two illustrations, and the absence of a cladogram based on more recent analysis), but Himstedt includes information on the Jurassic fossil caecilian with limbs, *Eocaecilia*, refers to recently published phylogenies based on molecular data, and comments on relationships of caecilians to other fossil and recent amphibians.

The third chapter, on the classification and geographic distribution of caecilians, is a general overview of the current taxonomy of caecilians. Himstedt notes that one should regard the classification that he presents as provisional, with considerable work remaining to be done on these little-known amphibians. Himstedt lists each family and its included taxa, with general comments on the key characters for each group. A general distribution map for each family, with brief discussion in the text, is included.

The fourth chapter, on the structure and function of organ systems, is a review of work on the skin and scales, the skeleton and musculature (including an extensive discussion of feeding mechanics), the intestine and lungs (including past and some recent physiological work on the latter, and reference to the recently described lungless species), the heart and circulatory system, the urogenital system (including reproductive cycles), and the brain and sense organs. The latter part on the nervous system is nearly 40 pages long, and includes considerable material and especially features Himstedt's thoughtful consideration of the structure and function of the eye and the tentacle, the former with comparison to the condition in salamanders, and the lateral line system. Himstedt is by training a neurophysiologist, and much of his analysis is based on his original work on caecilians. However, the discussion presented in this little book extends and integrates his work with that of others, and presents a synthetic approach to the neurobiology of these animals.

A short chapter on reproduction and development reviews much of the older and recent literature, and includes Himstedt's own observations, some, but not all, previously published. The chapter on the habits of caecilians is both a useful review of the literature on the ecology, life histories, and population biology of caecilians (and such literature is woefully limited, the Sarasins again having set the standard) and a presentation of Himstedt's own observations of the biology of *Ichthyophis kohtaoensis* based on his extensive field work in Thailand. Considerable new information about that species is presented; unfortunately, the two photographs of the field sites, while informative, did not reproduce well. The chapter on diet and prey capture is very short, slightly more than one page. Himstedt comments on the paucity of literature in this area, while summarizing much of the 100 years of data (mostly since 1970) that do exist on the termites, worms, and other terrestrial/fossorial animals that apparently compose the diet of caecilians. The chapter on burrowing behavior is inclusive of most of the information on burrowing mechanics, morphology, and comparisons among species, and adds new information from Himstedt's lab on the behavior of *I. kohtaoensis* in its tunnel systems. The short chapter on diel activity is similarly informative, and based largely on new information that Himstedt and his colleagues have gathered. Unfortunately, two recent papers on such activity in *Typhlonectes* were published too recently for Himstedt to have included them, but pose an interesting comparison the reader should consult.

The tenth chapter, on danger to and protection of caecilians, is an informed consideration of the apparently increasing rarity of caecilians as tropical habitats are progressively degraded. Himstedt presents information on the state of Thailand's forests, and cites the effect of a major monsoon and its consequences. He briefly compares Thailand with other southeast Asian countries, and closes with a plea for protection and the establishment of reserves so that such species as caecilians will be able to survive locally.

The final chapter deals with holding and breeding caecilians in captivity. He describes appropriate terrarium conditions for terrestrial species, including soil, humidity, water, and food, and presents comparable information for aquaria for aquatic caecilians. For each "set", he considers conditions for breeding caecilians, and he describes the work in his laboratory using endoscopy to examine the reproductive condition of males and females.

Himstedt is one of a small group of researchers who are exploring methods for breeding caecilians in order to provide both specimens for basic research and as means of conservation of the animals.

All in all, Himstedt's little book is a treasurehouse of new information and a synthesis of the literature, done in a scholarly way but one that should have broad appeal and readability. Some of the literature that might have provided useful information is not included, but Himstedt's selection is true to his goal. In addition, several recent publications on morphology, physiology, systematics, and behavior of caecilians appeared too late to be included, but they are part of the relative explosion of interest and information about the heretofore largely neglected caecilian amphibians. Himstedt's conscientious book provides the layperson and the professional with a ready update and background for the new work, and I trust he will continue his own outstanding research on caecilians. My only concern about this book, which deserves an extended audience and a long life, is that it is published only in German, presumably, and understandably, in large part for the increasingly large group of hobbyists who keep caecilians in captivity. The book is excellent for that purpose, as I have indicated, but it is much more than that—it is a compendium that belongs in the hands and before the eyes of anyone at any level of expertise who is interested in the biology of amphibians, tropical biology and conservation, morphology, physiology, and evolution. I urge everyone who reads German and shares these interests to buy the book, and those of you who would like to see English, Spanish, French and other translations to notify the publisher, so that new editions in these languages will be available very soon.

A Guide to the Reptiles and Frogs of the Perth Region by Brian Bush, Brad Maryan, Robert Browne-Cooper, and David Robinson. 1995. University of Western Australia Press, Nedlands, Western Australia (distributed in the USA by International Specialized Book Services, Inc., 5804 N.E. Hassalo St., Portland, Oregon 97213-3644, USA) xiv + 226 pp. Softcover. US $19.95. ISBN 1-875560-42-4.

AARON M. BAUER
Department of Biology, Villanova University
800 Lancaster Avenue, Villanova, Pennsylvania 19085-1699, USA
e-mail: abauer@king-kong.vill.edu

Australia continues to be the source of a seemingly limitless number of popular and semi-technical herpetofaunal guides of high production quality. Here is another. The book covers the herpetofauna of a region of Western Australia radiating out from the city of Perth to Yanchep in the north and Mandurah in the south, and from the western slopes of the Darling Range to Rottnest and Garden Islands. The region is the most often visited part of Western Australia, and although it lacks many of the more spectacular forms inhabiting the Pilbara and Kimberley regions of tropical Western Australia, it has an especially high level of endemism.

The book covers almost 100 species including 16 frogs (all but two of which are myobatrachids), two chelids (*Chelodina oblongata* and the extremely rare *Pseudemydura umbrina*) , 52 lizards (27 skinks, 11 geckos, eight pygopods, three agamids and three varanids), and 26 snakes (15 elapids, six hydrophiids, three typhlopids, and two pythons). Keys and brief familial and generic synopses are provided but the species accounts form the core of the book. These are concise and include subheadings for habitat, description, and general comments (ecology, reproduction, diet, etc.). For frogs the general comments are replaced by a "mating call and breeding biology" section. All terrestrial species have their own accounts and are accompanied by one or more color photos (up to four, as in the case of the western brown snake, *Pseudonaja nuchalis*) and an outline map of Western Australia with the species' range shaded. In the case of sea snakes, however, a separate account is provided for only one of the six species, *Pelamis platurus*, and although a key to four sea turtles is provided, only an extralimital (Broome) specimen of *Chelonia mydas* is figured, and no individual species accounts are presented. Dangerously venomous snakes are marked as such in the guide and receive the most detailed treatment of any of the included taxa, including brief comments on venom.

Other sections of the book include an overview of habitat types encountered in the Perth area (supplemented with seven representative color photographs), and a review of the conservation of amphibians and reptiles that criticizes the existing legislation in Australia for being too restrictive of serious amateur naturalists and for favoring the protection of individual species over the more essential protection of habitats. There are also sections on snake bite and snake-human and snake-pet interactions, with first aid measures conveniently summarized on the last two pages of the book for easy emergency use.

The guide concludes with a glossary of 300 terms, aimed largely at the novice, an index to subjects (incomplete) and common and scientific names, and a reference section. Those hoping for a comprehensive bibliography for the region will be disappointed. Only 41 technical references are cited, six specific to the Perth area, and the remainder more general. Frog references are especially scarce. General Australian herp works are referenced separately, and most major works are included, although the contributions of Harry Ehmann and Mike Tyler to the *Encyclopedia of Australian Animals* series are not (see Bauer, 1993 for references to these and other Australian herp books).

The book is attractively laid out and photo quality is consistantly high throughout. The value of the photos is increased by a feature rarely seen in comparable guides, the indication of the locality associated with each photographed specimen. The few line drawings are also well-executed, but the range maps are too small to show distribution patterns within the Perth region itself. The quality of the text and accuracy of information is generally good, but there are some problems. For example, the erroneous belief that the setae of gecko scansors function as pitons to gain purchase in minute irregulatities on smooth surfaces is promulgated. My greatest complaint, however, is that the generic names used do not consistantly follow Cogger (1992), nor do they always follow the most recent systematic treatments. Thus, among geckos *Strophurus* is employed for the "tail-squirting" *Diplodactylus*, but *Phyllodactylus* is used in preference to *Christinus*, as is *Underwoodisaurus* instead of *Nephrurus* (for *N. milii*).

Do you need this book? Unless you plan to visit the Perth region, can't get enough of Australian herp photos, or are bibliomaniacal, probably not. On the other hand, this very aesthetically pleasing guide is cheap and provides a user-friendly alternative to the more technical works on the Western Australian herpetofauna by the late Glenn Storr and his colleagues.

PETER A. MEYLAN
Natural Sciences, Eckerd College
St. Petersburg, Florida 33711, USA
e-mail: meylanpa@eckerd.edu

This book was compiled on the premise that a set of brief anatomical descriptions, combined with line drawings of turtle shells, constitutes a useful aid to the identification of turtle material from archaeological sites. It consists of 31 pages of double spaced text, 7 tables, 69 figures, and 6 maps. Forty-six of the figures are exploded views of carapaces or plastra rendered as unweighted line drawings. Most of the remainder are black and white photos of a single skeletal element from 13 different North American turtle taxa.

The text is superficial, especially when describing skulls and non-shell postcrania. There is little attempt to use the existing terminology for turtle skeletal morphology. Instead, a number of novel anatomical terms are introduced such as double track and single track vertebrae, stair stepping peripherals, pads (for dermal callosities in trionychids), and scute lines (for sulci). The authors also seem to have trouble with the singular versus plural forms of the terms scapula, ulna, epiplastron, and numerous others. An emydocentric view of turtle skeletal morphology, extensive use of secondary references, and poor writing all reduce the value of the text.

The authors are also clearly behind in their turtle taxonomy. The genera *Pseudemys, Trachemys,* and *Apalone* are not used. *Xerobates* is thought to include a single species, not two; *Chrysemys* (*sic*) *concinna* is equated with *Pseudemys texana*, and *Apalone*, it is said, has subsumed *Trionyx spiniferus*. Even common names suffer; the name Loggerhead Snapping Turtle is given for *Chelydra*.

This book contains too many mistakes. A plate of pubes (Fig. 15) is labeled as ischia, and a plate of ischia (Fig.16) is labeled as pubes. Descriptions in the text make it clear that the authors have these elements confused. An anomalous suprapygal of a *Gopherus berlandieri* is identified as a neural; it is suggested that Meylan (1987) justified the use of the term *Apalone* using biochemical characters (that is yet to come); and the oldest chelydrid is said to be Pliocene (Erickson 1973, describes a Paleocene form). Furthermore, the authors miss some good characters for identifying fragmentary turtle shell material such as the fusion of the shell of *Terrapene*, the large, continuous, dorsal keels on any costal bone of *Macroclemys*, and the hypo-xiphiplastral hinge in *Kinosternon*.

This book is a clear indication of why the peer-review process is a good idea. In their "final remarks," the authors suggest making identifications using this atlas and "most importantly, by making direct comparisons with a reference collection." I would have to suggest skipping directly to the second step.

The Hebrew University of Jerusalem, 91904 Jerusalem, Israel
e-mail: yehudahw@vms.huji.ac.il

Reptiles are relatively hardy in transportation. Only half a century ago, before the global rise of conservation and decline of postal services, it was normal to exchange live reptiles by international mail, not necessarily airmail. Now two modern processes are both countering and stimulating each other. On the one hand, most countries restrict collecting and exporting; on the other hand, herpetoculture is spreading. The blooming amateur market annually cycles millions of dollars in the United States alone. Some of its global volume in terms of herpetofauna has been reviewed for 1980–1985 by Luxmoore et al. (1988). This market, with its appetite for rarities, has stimulated, besides more positive results, the related phenomena of illegal collecting, trading, and smuggling, all of which are facilitated by the portability of reptiles (Hoser 1993).

Bureaucratic systems of licensing and inspecing have mushroomed almost everywhere. The mix of extensive legislation, haughty authority, insatiable desires, and ample money has generated its natural parasitic fauna of high-handedness, fanatic enforcement, corruption, and bribery—in some countries more than in others. It must have come as a shock to many readers of "Smuggled" (Hoser 1993; reviewed by Werner 1995), when Australia, celebrity of nature protection, was exposed by Raymond Hoser as a focus of negativity. It transpired that not only was smuggling of the endemic protected fauna rampant but many officials of governmental nature conservation agencies found a variety of ways to personally gain from it. Not merely bribery but perjury, violence, robbery, and even murder crowd the pages of "Smuggled" and make it a suspense story.

"Smuggled-2" is a sequel and like many a sequel is somewhat weaker than the initial book, perhaps mainly because the surprise element has dimmed. Still, it is compellingly interesting.

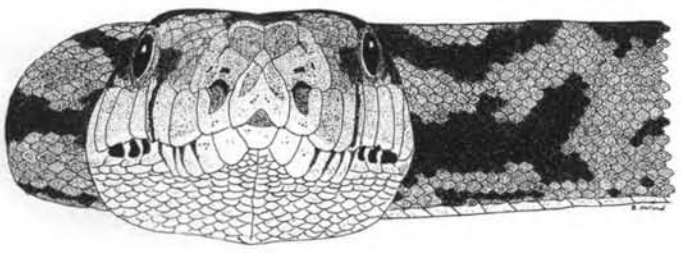
The twenty chapters may be seen as five clusters, each of which doubles as a separate appendix to "Smuggled." (I) Prefaces by others and chapters 1–3 depict the author's fight for legitimate (rather than illegal) conservation (especially in Australia), culminating in his "Smuggled," and the illegal war which aggrieved officials tried to wage against writing, publishing, and circulating the book. (II) Chapters 4–5 update the reader on the progress of inquiries into wildlife smuggling and related corruption, originally reported in "Smuggled." (III) Chapters 6–15 bring a deluge, in quantity and variety, of conservation-related crimes in Australia, often with the involvement of officials. Mixed in are some occurrences of possibly less criminal incompetent bungling of conservation authorities. Some of the contents is fresh, having occurred after the publication of "Smuggled." Other cases actually had occurred earlier, and it was the reading of "Smuggled" that stimulated witnesses to speak up. (IV) Chapters 16–17 widen the scope to encompass wildlife poaching in Africa and the astonishing Madagascar fiasco (March 1993), when police shot four visiting herpetologists, already prostrate by order, killing two and crippling the well-known F. J. Obst. (V) Chapters 18–19 consider

prospects for the future, including the potential of captive breeding for saving species. There is no index.

The bibliographies of published and unpublished source materials (Chapter 20; 29 pages), are intended to testify to every word in the book. Unfortunately the sources are not numberred and usually the text does not guide the reader to them. Still, everything appears to be true, because otherwise even in the most liberal of countries, no author could retain impunity, shooting such barrages of accusations at officialdom. In fact, Hoser's very ability to speak up (despite being harrassed for this) attests to the basic rectitude of the country, so many of whose emissaries are shown to be wrong doers.

The text is enriched with some 125 black-and-white photographs. These are not numbered and don't shine on the dull paper but they are fully explained and materially help in conveying the message. Most of the figures fall into one of four classes: "Good guys" (27 persons fighting corruption, innocent victims of corruption, etc.); "bad guys" (26 corrupt or allegedly corrupt nature inspectors and politicians, etc.); problematic animals and plants and equipment for smuggling them (39 figures); documents (24 newspaper clippings, letters to or from authorities, etc.).

Hoser fights on behalf of the animals and the lovers of animals, both against mercenary exploiters of fauna and flora and against fanatic or corrupt conservation-bureaucrats. I share his attitude that this is a war of light against dark. But I think that sometimes the light dazzles him. For example, he seems to imply that some confiscated animals should have been released into the wild, which is controversial in terms of population genetics and long-term effects. He assaults with a fervor that scorns the careful use of commas, apostrophes, and sometimes prepositions.



But all in all, assuming you are interested in conservation, if you have read "Smuggled" you will probably want this follow-up; if you have not read "Smuggled," then reading at least Smuggled-2 is a must.

The Galápagos are perhaps the most biologically famous of all island groups. The leading citizens of Galápagos are the giant tortoises, once called *Geochelone elephantopus*, now generally referred to as *Geochelone nigra*. Efforts by systematists to chart the evolution of Galápagos tortoises have been made difficult by many unfortunate events. Inadequate records, some centuries old, and the decimation of populations by pirates, poachers, and introduced animals have made it difficult to prepare a monographic revision. Even pulling together all the literature, finding specimens previously mentioned, and interpreting an often arcane scientific past can be intimidating.

To everyone's benefit, Peter Pritchard has prepared a useful literature survey. It will be possible for a future systematist to do a thorough job of revising this highly variable lineage. Many interesting speculations are presented by Pritchard. Although none are subjected to test, circumstanial evidence supports some of his hypotheses. Pritchard's personal viewpoints are evident. His well known rejection of modern cladistic methods is especially anachronistic (see page 30), but then the science of systematics has never been his strong suit. Rather, Pritchard has carefully and quite admirably canvassed an old and often vague literature. Alas, clarity has not yet been achieved for a variety of reasons.

Pritchard is an engaging writer prone to romantic images presented with an ease of communication rare among scientists, but he does not consistently provide the details one expects in scientific contribution. Frequent qualitative assessments, rambling but readable prose, and practically no quantitative or statistical evaluation make it impossible to recognize this work as a modern monographic revision. For example, he suggests that the first tortoises to reach Galápagos were already giants. Unfortunately, no real test of such an assertion is provided. No phylogenetic hypothesis is provided to demonstrate the relative size of the sister taxa of *Geochelone nigra*. No statistics are provided to illustrate the current range of size in *G. nigra* populations, or to document that there exist statistically significant differences among populations. The suggestion that dwarfism might be more likely once the archipelago was colonized, although possible, must be recognized for what it is—an intriguing, but unsupported, speculation. Pritchard's book is a good literature survey, but it does not fill the need for a modern, comprehensive, thorough, monographic revision of the Galápagos tortoises.

Although Pritchard claims the title of "first revisor" (see bottom of page 48), this work does not warrant the accolade. No list of diagnostic features is provided for each taxon. No key to the identification of specimens is presented. There is no list of specimens examined by Pritchard or any indication of how specimens

in well known collections (e.g. CAS, BMNH, USNM, AMNH, MCZ) ought to be allocated to the names he recognizes.

Here are a few minor quibbles. Except for a very few photographs of type material and an illustration that appeared in another publication, most of the pictures do not identify the tortoises using Pritchard's Latin names. None of the maps provide a scale bar, latitude or longitude marks, or a compass direction. Not all the maps consistently provide topographic relief, nor is the interval for topographic lines, when present, indicated in all maps. In fact, if it had been possible (I suspect it was not), I would have prerferred range maps that indicated both collection points and expected distributions.

I found Pritchard's detailed critique of Garman (1917) to be an odd indulgence. Despite Garman's deserved and secured position in the history of herpetology, this 1917 paper is an unfortunate contribution to the literature on Galápagos tortoises. Pritchard's valuable time could have been better spent. Both Van Denburgh's (1914) and Rothschild's (1915) earlier studies are better and of the same vintage. Also, I could not agree with Pritchard's characterization of my work, which leaves me wondering if he misinterpreted the results of others.

One final quibble—to be politically correct—why did Pritchard elect to preferentially use Anglicized island names? The Ecuadorian government has devoted a great deal of time and scarce financial resources to the conservation of Galápagos. It would have been a courtly gesture to recognize the appropriate Spanish names for all the islands as primary. Certainly the parenthetical use of the English names would have been better for recognizing Ecuador's sovereignty over Galápagos.

I am sure that most readers of this review will recognize many of the above comments as little more than picky and obsessive. Anyone who knows people interested in turtles will recognize the sort of person likely to make them. However, I do hope that a few of the points I have made will be taken seriously enough to result in the sort of monograph that Galápagos tortoises deserve.

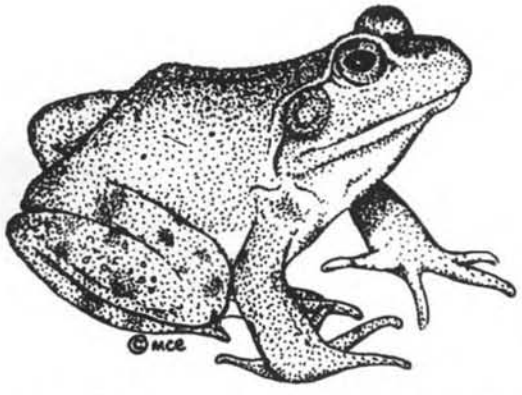
310 Malibou Boulevard
Houma, Louisiana 70364-2598, USA

This 8 1/2 x 11-inch paperback is a compilation of 104 keys to the amphibians and reptiles of México that have appeared in numerous publications since 1945, as well as including 16 keys presented for the first time. Some keys cover only certain parts of some genera. Three of the older keys have been modified. All previously-published keys are used with permission of authors or publishers, and original authors are listed for each key. The older keys are electrostatic copies of the originals, thus the printing throughout varies according to the quality and style of the original.

Previously published keys for the most part have not been modified to reflect current taxonomy, though notes at the end update the classification and make the user aware of new taxa that have since been described. A breakdown of the keys have Anura with 19, Gymnophiona with 6, Sauria with 32, Serpentes with 33, Testudines with 13, and Crocodilia with 1.



In several instances the Spanish version of a key is presented when the original had both English and Spanish versions. New keys consist of those by J. R. Dixon (*Tomodactylus*; *Coleonyx*; *Phyllodactylus* for Baja California and mainland México); E. Pérez-Ramos and G. Casas A. (*Rana*); K. DeQueiroz (Mexican iguanas); C. Lieb (*Anolis*; *Eumeces*); A. Nieto-Montes de Oca (*Anolis schiedi* group, two keys); R. L. Bezy and J. L. Camarillo (Xantusiidae); J. D. Johnson (*Masticophis*); K. P. Kofron (*Sibon*); D. A. Rossman (*Thamnophis*); I. Goyenechea (*Conopsis* and *Toluca*). The keys to *Anniella* and *Ophisaurus* were adapted and translated into Spanish from the original by Walter Schmidt Ballardo and *Xenosaurus* by Edmundo Pérez Ramon and Lucía Saldaña de la Riva.

The publication begins with an index followed by an introduction in Spanish and a short section on literature cited. This is only for the literature cited in the introduction; many more publications are listed in the notes sections under various keys to update them. This is followed by nine plates of drawings showing characteristics of the various groups. Some additional plates are included with various keys.

As stated, 85 of these keys have been published previously, but the value of this publication is to have all of the keys at one's fingertips. Even the older keys work due to the accompanying notations (in Spanish). Anyone working on the Mexican herpetofauna will welcome this addition to the literature. The compilers have produced a very useful piece of work.

ERRATUM

In the two book reviews by Lamar and Liner (Herpetol. Rev. 27[2]:103), J. T. Collins erroneously was listed as the *editor* of the SSAR Common Names publication; instead, he should be listed as *author*.

Rana catesbeiana (Bullfrog). USA: New Hampshire: Wonalancet. Illustration by Mark C. Erelli.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). E-mail: ssar@sluvca.slu.edu.

Herpetological Review

Volume 28, Number 3 — September 1997

BRIEF RESUMÉ of the applicant or project coordinator. (F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed 1200 words, excluding title page, literature cited, resumé, and budget.

Applicants must designate to which of the six categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 DECEMBER 1997 to be considered. Failure to meet these guidelines may result in elimination of a proposal from consideration. The awards will be announced on or around 1 April 1998. Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Julian C. Lee, Chair, SSAR Grants-in-Herpetology, Department of Biology, P.O. Box 249118, University of Miami, Coral Gables, Florida 33124, USA. Tel. (305) 284-6420; fax (305) 284-3039; e-mail: jlee@umiami.ir.miami.edu.*

Grants-in-Herpetology Donations Sought

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible (for U.S. residents) contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

Thanks to Reviewers

The Editor and the Society acknowledge, with considerable appreciation, the assistance of the following individuals in evaluating manuscripts submitted to *Herpetological Review*. An * indicates consultation on two or more manuscripts.

Kraig Adler, Roger A. Anderson, David Auth, Ralph W. Axtell*, Breck Bartholomew, Aaron M. Bauer*, Bernard Bechtel, Daniel Beck, Trevor Beebee, Dale Belcher, Robert L. Bezy, Richard Bothner, David Bradford Laura Brandt, Alvin Braswell, I. Lehr Brisbin, Walter C. Brown, William S. Brown, Richard C. Bruce*, Bryant Buchanan, Kurt A. Buhlmann*, Gordon Burghardt, Vincent J. Burke, Stephen D. Busack*, David Cannatella, Paul Chippindale, Joseph T. Collins, P. Stephen Corn, Alan de Queiroz, Kevin deQueiroz, C. Sprackland, Samuel Sweet, Ian Swingland, Stephen Tilley*, Stanley Trauth, Bern Tryon, John K. Tucker, Jens Vindum, Laurie J. Vitt, Richard Vogt*, Jill Wicknick, John Wiens, and Larry David Wilson.

Illustrations Wanted for *HR*

We are always on the lookout for high quality illustrations of herpetological subjects for possible publication in *Herpetological Review*. Original drawings should be of a scale that would permit reduction to approximately 30 x 90 mm or smaller. Of particular interest are drawings of material for which locality data or museum catalogue numbers are available; this information should be included with the drawings. Original art (or good quality photocopies) should be packaged to ensure safe delivery and sent to the Editor (address on inside front cover).

NEWSNOTES

Varanid Society Newsletter

The first issue of *Varanids*, the quarterly newsletter of The Varanid Society, has just been published. The stated aim of the newsletter is to advance monitor research, including biology, husbandry, natural history, and conservation. To subscribe, send US $20 to: *The Varanid Society, 114-24 125th Street, South Ozone Park, New York 11420, USA.*

New Conservation Journal

Cambridge University Press, in association with the Zoological Society of London, plans to launch a new journal—*Animal Conservation*—in 1998. The aim of this new journal is to provide a forum for rapid and timely publication of novel scientific studies of past, present, and future factors influencing the conservation of animals species and their habitats. A central theme will be to publish important new ideas and findings from evolutionary biology and ecology that contribute towards the scientific basis of conservation biology. Full instructions for contributors can be found on the Internet at: http://www.cup.cam.ac.uk/journals/jnlscat/ani/anilFC.html.

Graduate Studies in Biological Conservation

The State University of New York at Albany now offers an interdisciplinary Master of Science degree that prepares students for careers requiring knowledge of both biology and public policy, in matters pertaining to biological conservation. Begun in 1996, the Biodiversity, Conservation and Policy Program teaches students how basic concepts in conservation biology, policy analysis, planning, and the political process interact during efforts to preserve species diversity and endangered habitats and ecosystems. To obtain further information about this program, contact:

Margaret M. Stewart, Program Director, Department of Biological Sciences, University at Albany, State University of New York, 1400 Washington Avenue, Albany, New York 12222, USA; e-mail: mstewart@csc.albany.edu or telephone: 518-442-4348.

Request for Box Turtle Photographs and References

Ken Dodd is writing a book entitled "The Natural History of North American Box Turtles." The book will include photographs of all living and fossil box turtles (genus *Terrapene*), in terms of identification, phenotypic variation, day to day activities (aggression, mating, egg deposition, etc.) and use/depiction in art or anthropology. Anyone willing to provide high quality color slides on a temporary loan basis should contact Ken by e-mail (kdodd@nervm.nerdc.ufl.edu) or regular mail at: *C. Kenneth Dodd, Jr., U.S. Geological Survey, Florida Caribbean Science Center, 7920 NW 71st St., Gainesville, Florida 32653, USA*. Any slides used will receive appropriate acknowledgment in the book.

Ken also is collecting pertinent references on box turtle biology, and would appreciate receiving copies of unusual citations, theses, papers in press, and unpublished reports. Spanish language references to the Mexican species are particularly sought. Send information to the address listed above.

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due by 15 October 1997, with notification by 1 December 1997. Grantees are expected to complete their Academy visit by 15 September 1998. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

MEETINGS

Meetings Calendar

3–5 October 1997—Second Annual Meeting of the Canadian Amphibian and Reptile Conservation Network and the 7th Annual Meeting of the IUCN/SSC Task Force on Declining Amphibian Populations in Canada (DAPCAN), Acadia University, Wolfville, Nova Scotia. Contact: Stan A. Orchard, Chairman, CARCN/RCCAR, 1745 Bank Street, Victoria, British Columbia, Canada V8R 4V7. Tel./Fax: (250) 595-7556; e-mail: sorchard@islandnet.com.

About Our Cover: *Ichnotropis capensis*

The lacertid genus *Ichnotropis* comprises a number of small, rough-scaled, terrestrial species inhabiting mesic and xeric savannah in central and southern Africa. The genus was last revised by Boulenger (1922), who recognized six species. Since then, additional species and races have been described, although there remains confusion in the literature concerning the number and diagnostic characteristics of the various taxa. A generic revision, including the description of a new species from Angola, is in preparation (Arnold and Branch, in prep.).

The genus is of further interest in containing a number of sympatric species that display a unique 'annual' reproductive strategy, in which their lives cycle asynchronously, thus reducing competition between them. The phenomenon was first described in two species by Don Broadley in Zimbabwe (Broadley, D. G., 1979. S. Afr. J. Zool. 14:133–138). Both species (*I. capensis* and *I. squamulosa*) mature within 5–8 months of hatching, and die soon after laying a single clutch (exceptionally two) of eggs. When they occur together, the life cycles of the two species are staggered, so that the juveniles and adults of both species are found at different times. Presumably this reduces competition for resources, but the phenomenon has been poorly studied, especially where the two species range out of sympatry. Full ecological understanding and analysis of this interesting phenomenon is hampered by taxonomic confusion within the genus, and the lack of a robust phylogeny.

The cover depicts a male Cape rough-scaled lizard (*Ichnotropis capensis*) in full breeding color. It was collected in October 1995 in dry sand forest outside Tembe Elephant Reserve in northern Zululand, Kwazulu-Natal, South Africa. Hatchling *I. squamulosa* were present at the time, but not adults, neatly illustrating the unique 'annual' cycling.

The cover photo was taken by **Bill Branch**, who was born in London but now lives in South Africa. He has been the herpetologist at the Port Elizabeth Museum, Eastern Cape Province, since 1979, has a broad interest in herpetology, and has authored four books on African reptiles, including the first field guide to the reptiles of the subcontinent (1988) and *Dangerous Snakes of Africa* (co-authored with Steve Spawls). His field guide is currently being revised, with the inclusion of over 80 new species! Currently, he chairs the IUCN SSC African Reptile and Amphibian Group.

We asked Bill about his set-up for photography. "There's not much to say about equipment. I have relatively basic stuff (the SA exchange rate is crippling!) consisting of a Nikon AF N6006 body and 55mm Micro Nikkor lens (which I use for 90% of my photography), now enhanced with a Nikon 1.4 teleconvertor TC-14A that Michael Fogden got for me. The main advantage of the teleconvertor is that it increases my working distance, allowing me to photograph small lizards from 6–10 inches. The latter has two advantages: the first is that I'm not 'sticking it up their nose' so they tend to behave a bit more naturally; the second, and possibly more important, is that it allows more space to get flash light from the front without working in the 'shadow' of the camera and lens. When using flash I use only a single light source (a Nikon speedlight SB-20 with SC-17 extension cord), not on the camera but on a small tripod placed at about 10 o'clock (i.e., coming over my left shoulder). I try to soften the harsh shadows by reflecting back with silver foil or white card. The film is the weakest element, and due to cost I have to use a local commercial Agfa film (ASA 100). I would love to be able to use better film. I'd give my right arm to afford Fuji's Velviglo!"

Separation and imaging of Branch's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida, USA.

18–19 October 1997—First International Symposium on Snakebite. Zhanjiang, People's Republic of China. Contact: Organizing Committee of the First International Symposium on Snakebite, No. 2 Cunjin Road, Zhanjiang City, Guangdong Province 524037, People's Republic of China. Tel./Fax 0086-759-3316724.

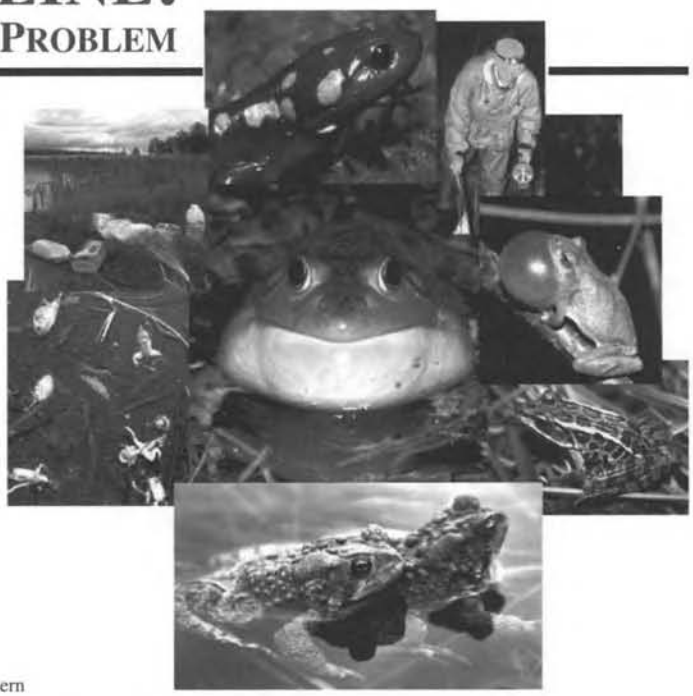
(510) 642-3567, Fax (510) 643-8238, e-mail: asiaherp@uclink2.berkeley.edu.

LEGISLATION & CONSERVATION

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. Please direct all communications to the Section Editor.



USA: Oklahoma: Current Oklahoma Department of Wildlife Conservation regulations protect all turtles under four inches and softshells over 18 inches from commercial harvest. However, legislation currently is being debated that would overturn these regulations and allow harvesting of turtles of any size. Earlier this year, the proposed legislation (bill HJR 1040) passed the Oklahoma House of Representatives (vote, 99–1) but was defeated by the Senate Wildlife Committee (vote, 6–4). Upon its defeat, HJR 1040 was tacked onto another, unrelated, bill (SB 196) that was meant to provide protection for Oklahoma paddlefish populations. Unfortunately, with the addition of HJR 1040, SB 196 forces a decision between protecting turtles or paddlefish that should not be necessary. In 1996, commercial turtle harvesters in Oklahoma reportedly grossed over $89,500 on the sale of 56,390 turtles. Most frequently sold were Red-eared Sliders (*Trachemys scripta*), which comprised 66% of the total harvest. The proposed legislation would not affect other Oklahoma regulations concerning the protection of alligator snapping turtles (*Macroclemys temminckii*), map turtles (*Graptemys geographica*), and chicken turtles (*Deirochelys reticularia*). For additional information, contact: *Richard L. Lardie, P.O. Box 9002, Vance AFB, Oklahoma 73705, USA.*

USA: U.S. Fish and Wildlife Service: The tenth regular meeting of the Conference of the Parties (COP10) convened 9–20 June 1997 in Harare, Zimbabwe to consider proposed amendments to CITES. The following results are for US proposals: twelve species of map turtles (*Graptemys* spp.) to Appendix II, defeated; alligator snapping turtles (*Malaclemys temminckii*) to Appendix II, withdrawn; timber rattlesnakes (*Crotalus horridus*) to Appendix II, withdrawn. Summaries of the above proposals can be found in Federal Register, Vol. 62, No. 73, 16 April 1997, pp. 18565–18567 (see also Herpetological Review, Vol. 28, p. 6). Additionally, a proposal by Cuba that would have transferred Cuban populations of Hawksbill Sea Turtles (*Eretmochelys imbricata*) from Appendix I to II was defeated. More information concerning COP10 and CITES may be found at an Internet site maintained by the U.S. Fish and Wildlife Service: http://www.fws.gov/~r9dia/cites.html.

First Volume in a New Series on Conservation by the Society for the Study of Amphibians and Reptiles

AMPHIBIANS IN DECLINE:
CANADIAN STUDIES OF A GLOBAL PROBLEM

THIS VOLUME, WRITTEN BY MORE THAN 50 OF CANADA'S leading herpetologists and conservationists (representing DAPCAN, the Canadian Working Group of the IUCN Declining Amphibian Populations Task Force), includes topics of broad worldwide interest and application. These include dispersal, fluctuations, genetic diversity, monitoring of natural populations, as well as effects of temperature, acidity, pesticides, UV, forestry practices, and disease.

Published by SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in cooperation with the CANADIAN ASSOCIATION OF HERPETOLOGISTS and the WORKING GROUP ON AMPHIBIAN AND REPTILE CONSERVATION IN CANADA

Edited by David M. Green
McGill University, Montreal

CONTENTS

Foreword. **W. Ronald Heyer**
Preface. **David M. Green**
Amphibian Pond Communities in Southwestern Ontario. **Stephen J. Hecnar**
Fluctuations in Abundance and Age Structure in Three Species of Ranid Frogs in Algonquin Park, Ontario, from 1985 to 1993. **Leonard J. Shirose and Ronald J. Brooks**
Population Characteristics of the Red-spotted Newt, *Notophthalmus viridescens*, at the Mastigouche Reserve, Québec. **Raymond Leclair, Jr. and Maria Helena Caetano**
Population Biology of the Long-toed Salamander (*Ambystoma macrodactylum*) in the Front Range of Alberta. **G. Lawrence Powell, Anthony P. Russell, Janice D. James, Stephen J. Nelson, and Sheri M. Watson**
Temporal Variation in Abundance and Age Structure in Fowler's Toads (*Bufo fowleri*) at Long Point, Ontario. **David M. Green**
Fluctuations in a Northern Population of Gray Treefrog, *Hyla versicolor*. **Susan Bertram and Michael Berrill**
Northern Leopard Frog (*Rana pipiens*) Dispersal in Relation to Habitat. **Carolyn N.L. Seburn, David C. Seburn, and Cynthia A. Paszkowski**
Distribution and Abundance of the Chorus Frog, *Pseudacris triseriata*, in Québec. **Claude Daigle**
Flow Cytometric Analysis of Amphibian Population Composition. **Timothy F. Sharbel, Leslie A. Lowcock and Robert W. Murphy**
The Value of Monitoring Genetic Diversity: Distribution of Ambystomatid Salamander Lineages in Ontario. **Leslie A. Rye, Wanda J. Cook, and James P. Bogart**
Amphibians of Newfoundland and Labrador: Status Changes Since 1983. **John E. Maunder**
Amphibians in the Northwest Territories: a Summary of Historical Information. **Michael A. Fournier**
Amphibians in Southwestern Yukon and Northwestern British Columbia. **Lee Mennell**
Status of Amphibians in Saskatchewan. **Andrew Didiuk**
Historical Evidence Does Not Suggest New Brunswick Amphibians Have Declined. **Donald F. McAlpine**
Surveying Calling Anurans in Québec Using Volunteers. **Michel Lepage, Rhéaume Courtois, Claude Daigle, and Sylvie Matte**
Anuran Species Richness in Agricultural Landscapes of Québec: Foreseeing Long-term Results of Road Call Surveys. **Joël Bonin, Jean-Luc Desgranges, Jean Rodrigue, and Martin Ouellet**
Extensive Monitoring of Anuran Populations Using Call Counts and Road Transects in Ontario (1992 to 1993). **Christine A. Bishop, Karen E. Pettit, Mary E. Gartshore, and Duncan A. MacLeod**
Non-disruptive Monitoring of Terrestrial Salamanders with Artificial Cover Objects on Southern Vancouver Island, British Columbia. **Theodore M. Davis**
Testing the Efficiency of Artificial Covers to Survey Terrestrial Salamanders in Québec. **Joël Bonin and Yves Bachand**
A Simple Transect Technique for Estimating Abundances of Aquatic Ranid Frogs. **Donald F. McAlpine**
Effects of Logging on Terrestrial-breeding Amphibians on Vancouver Island. **Linda A. Dupuis**
The Impact of Forestry Practices upon Amphibian Populations in Eastern North America. **Ruth Waldick**
The Vulnerability of Amphibians in Canada to Global Warming and Increased Solar Ultraviolet Radiation. **Kristiina Ovaska**
The Effects of Temperature and Acidity on Spawning of the Spotted Salamander *Ambystoma maculatum* in Fundy National Park. **Douglas Clay**
Effects of Pesticides on Amphibian Embryos and Tadpoles. **Michael Berrill, Susan Bertram, and Bruce Pauli**
Measuring the Health of Frogs in Agricultural Habitats Subjected to Pesticides. **Joël Bonin, Martin Ouellet, Jean Rodrigue, Jean-Luc Desgranges, François Gagné, Timothy F. Sharbel, and Leslie A. Lowcock**
Diseases in Canadian Amphibian Populations. **Graham J. Crawshaw**
Assessing and Controlling Amphibian Populations from the Larval Perspective. **Richard J. Wassersug**

INSTITUTIONAL PROFILE

The Lizard Collections of the National Museums of Scotland

ROBERT GEORGE SPRACKLAND*

and

GEOFFREY N. SWINNEY

National Museums of Scotland, Chambers Street, Edinburgh EH1 1JF, UK

**Present address: Young Forest Company, 951 Old County Road, Suite 134, Belmont, California 94002, USA*

e-mail (RGS): 102175.1650@compuserve.com

e-mail (GNS): gns@nms.ac.uk

This note introduces the lizard collections of the National Museums of Scotland. The collection, which comprises about 3070 individual specimens in 2350 lots, recently has been re-housed and extensively re-curated. All the material has been examined and identifications confirmed or reassigned, mainly by the senior author. The newly refurbished premises provide facilities for visiting researchers. During the re-curation process most wet-preserved specimens have been transferred to new glassware and all specimens have been catalogued into the Museum's database, thus improving access to both specimens and their associated data. A brief outline of the scope of the collection is given below.

The Natural History collections have their origins in those amassed by the University of Edinburgh and transferred into public ownership to form the Industrial Museum of Scotland and the Natural History Museum, Edinburgh in 1855. No lizard specimens survive from the original University collections. The earliest lizard specimen that now can be located in the collection is a specimen of *Polychrus marmoratus* (L.) which forms part of a small collection registered as 'A number of snakes [sic] from Trinidad' presented in 1856 by a Mr. G. P. C. Murray, a student at the University. Since that time the institution has undergone several changes of name, becoming successively the Edinburgh Museum of Science & Art (1864–1904), the Royal Scottish Museum (1904–1985), and the National Museums of Scotland (1985 to present). For a brief history of the collections see McGowan et al. (1990).

The only type material in the lizard collection is a paratype of the gecko *Tropiocolotes (Asiocolotes) depressus* Minton and Anderson, 1965, NMSZ 1964.58.1, presented by Jeremy A. Anderson. However, an unusually large gecko from Jamaica, discovered in the collection during the re-curation process, is thought to represent a new species and will be described shortly (Sprackland and Swinney, in prep).

About 100 donors and vendors have contributed specimens to the collections. Although the Museum had never had a herpetologist on staff it has attracted the donation of several large collections of reptiles. Most notable are those of Sir Andrew Smith, Sir Malcolm Donald MacEacharn, and Jeremy A. Anderson. Together these three collections make up 80% of the lizard collection.

Sir Andrew Smith (b. 1797; d. 1872) trained in Edinburgh and joined the army medical service as a Temporary Hospital Mate in 1815. He went on to rise to the rank of Director General of the Army Ordinance and Medical Departments. During his early and mid-career (1821–1837) he was stationed in South Africa where, in addition to his military duties, he was instrumental in founding the South African Museum and was its first honorary Superintendent. Through his interests in natural history he became the pre-eminent authority of his day on the fauna of southern Africa and the author of a five volume work, "Illustrations of the Zoology of South Africa" (Smith 1838–1849). He participated in several expeditions and led the 1834–1836 expedition into the Transvaal organized by the Cape of Good Hope Association for Exploring Central Africa (Kirby 1965; Smith et al. 1975). Following its exhibition at the Egyptian Hall in London, much of the material collected on the Association's expedition was sold at auction in London in June 1838 (Chalmers-Hunt 1966; Kirby 1965). Smith, however, maintained his own collection of reptiles. In 1859 his health was failing, whereupon he donated this collection, comprising 1700 lots which included 1010 lizards (in 545 lots), to the Museum. The collection is registered as NMSZ 1859.13. Although it contains some southern African material—including primary types, although none of lizard taxa—much of the collection is worldwide. Unfortunately, it is generally poorly labeled, perhaps reflecting Smith's poor state of health—some specimens have more precise locality data than others, whereas most are without data. About half the specimens carry no locality data while many others give only the most general locality information (e.g.. 'South America,' 'Australia,' etc.).

Jeremy Andrew Anderson, who is still an active collector resident in Pakistan, between 1962 and 1968 donated a large number of specimens, mostly collected from the Baluchistan and Sind. They are registered as NMSZ 1962.9, 1962.21, 1962.26, 1962.47, 1963.1, 1963.2, 1963.20, 1963.23, 1963.25, 1963.33, 1964.58, 1965.36, 1968.13, 1969.15, and 1989.49. (This last batch was received in 1963 but at that time allocated a register number, 1963.33, which had already been used for a different batch). In correspondence that accompanied the collection, Anderson notes that prior to collecting for the National Museums of Scotland (then the Royal Scottish Museum) he had sent extensive reptile collections to the 'Laborotoire d'Erpetology, Paris' (sic; letter from Anderson to A. S. Clarke, 29 March 1962). The collections he sent to Edinburgh in total numbered about 2040 herpetological specimens, 1390 of which are lizards. All the specimens carry locality data and some of the batches were accompanied by detailed field notes (NMS Natural History Archives File No. 183). Specimens from this collection were noted by Minton (1966), although sometimes with incorrect registration numbers, and currently are being studied by Steven C. Anderson (no relation to Jeremy A. Anderson).

Sir Malcolm Donald McEacharn (b. 1852; d. 1910) was born in London of Scottish parents. His business interests, initially in shipping but later diversifying into other areas, led him to settle in Melbourne, Australia, where he entered politics (Dunstan 1986). He amassed a collection, mainly of birds but also other natural history and ethnographical material. At least some of his collection he bought from G. A. Keartland, naturalist both to the Horn Expedition to Central Australia and the Calvert Expedition to northwest Australia, in 1894 and 1895 respectively (McEvey 1983). The collection, which contained 84 lots of lizards, was donated to the Museum by McEacharn's widow and son in 1925. It is registered as NMSZ 1925.9. A notebook accompanying the collection (NMS Natural History Archives File No. 25/35) gives collection data for a few of the lizard specimens but most of the collection has no specific locality data.

The re-housing and computerized documentation of the collection facilitates improved access and faster response times to inquiries about specimens held. During 1995, the majority of the herpetological collections were moved to new research and hold-

ing facilities at West Granton, providing roomier facilities for visiting researchers. The Museum welcomes inquiries and is keen to promote the use of its holdings in taxonomic and other research activity. We invite requests from researchers for use of the material. These should be addressed to the second author.

Acknowledgments.—We are grateful to Angus Kneale for technical assistance in computerization of the catalogue of lizards. The first author also thanks James Macdonald for numerous courtesies to facilitate work while at West Granton.

Director, Highlands Biological Station
University of North Carolina

The University of North Carolina General Administration is seeking an Executive Director for its field station, the Highlands Biological Station at Highlands, North Carolina. The position will be at the Associate or Full Professor level with the applicant holding an academic position at Western Carolina University or another appropriate institution. (For example, the current retiring Executive Director has an academic appointment at Western Carolina University and spends one-half of his time during the academic year and full time during the summer on Station duties). Applicants should possess a Ph.D. degree and have considerable experience with graduate training, instruction, and administration. A strong research program and successful grantsmanship and fund raising also are important requirements for this position. The applicant's field of research should be in the biological sciences, especially in an area of ecology, behavior, or systematics and evolution. The appointment will begin July 1, 1998. Applicants should submit by November 30, 1997 a detailed CV, a statement of their research and future research plans, a statement of their administrative experiences as well as arrange to have three letters of reference sent to: *Dr. Alan E. Stiven, HBS Search, Department of Biology, University of North Carolina, Chapel Hill, North Carolina 27599-3280, USA.*

The Highlands Biological Station was founded in 1927. It is a regional field station for biological research and education in the southern Appalachian Mountains. As an interinstitutional center of the University of North Carolina, it is administered by Western Carolina University, a constituent institution located in nearby Cullowhee, NC. The facilities of the Station are available for year-round use by qualified scientists engaged in research on the biota and environments of the southern Appalachian region. Courses in various areas of field biology are offered in the summer to both undergraduates and graduate students by visiting instructors. The Highlands Biological Station's website can be viewed at http://www.wcu.edu/hibio. The University of North Carolina is an equal opportunity-affirmative action employer.

A New Publication from the
Society for the Study of Amphibians and Reptiles

GRANTS AND AWARDS FOR HERPETOLOGISTS

by

Joan C. Milam

with a foreword by Alan H. Savitzky, Past President, SSAR

Featuring a detailed listing of the title, granting agency, description, eligibility, restrictions, deadlines, contact addresses, and phone numbers of nearly 100 Grants, Awards, Funds, Fellowships, Scholarships, Travel Awards, and Internships of interest to all herpetologists.

A valuable resource for students, professionals, amateurs, and regional societies.

US $10 per copy (postage included)

Send orders to: Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, St. Louis, MO 63103, USA. Telephone: (314) 977-3916; FAX: (314) 977-3658; e-mail: ssar@slu.edu. Make checks payable to "SSAR." Orders may be charged to MasterCard or VISA (please provide account number and card expiration date).

Alligator Attacks on Humans in the United States

MICHAEL R. CONOVER
and
TAMI J. DUBOW
Jack Berryman Institute, Department of Fisheries and Wildlife
Utah State University, Logan, Utah 84322-5210, USA

American alligators (*Alligator mississippiensis*) have posed a threat to human safety since Native Americans first settled within their range. Early explorers of Florida reported that both they and the Natives considered alligators dangerous and took precautions to minimize the threat (Le Moyne 1591; Van Doren 1955, as cited by Hines and Keenlyne 1977). However, this threat diminished during the 1800's and 1900's, owing to the collapse of the alligator population from hunting. During this period, alligators were confined to remote swamps where contact with humans was unlikely. This changed, however, beginning in 1969 with the passage of the Lacey Act Amendment, which effectively curtailed interstate shipment of illegal alligator hides, and with the passage of the Endangered Species Act in 1973. With alligator populations recovering, attacks on humans have become more common. Concomitantly, human populations and residential development of waterfront property have increased.

Yet, despite the sensational nature of an alligator attack on a human, we are aware of only two published papers in the scientific literature dealing with the subject; both were published almost 20 years ago and dealt with attacks in Florida (Hines and Keenlyne 1976, 1977). The object of this paper was to compile statistics about the frequency of alligator attacks of humans in the U.S. Our interest was to determine the frequency of alligator attacks on humans, identify characteristics of attacking alligators and their human victims, assess whether the number of attacks has increased recently, and determine what percentage of alligator attacks resulted in a human fatality.

TABLE 1. Summary of alligator attacks on humans in the U.S. Data were provided by the different state wildlife agencies (see acknowledgments). For all states, it is unclear when record keeping began. Hence, the period for each state begins with the first documented attack.

State	Period	No. attacks	Human fatalities
Alabama	?? –1995	4	0
Florida	1948–1995	218	7*
Georgia	1988–1995	5	1
Louisiana	1978–1995	1	0
South Carolina	1976–1995	6	0
Texas	1980–1995	2	0
Total		236	8

*These statistics exclude seven fatalities in Florida for which it could not be determined if the alligator attack caused the victim's death or if the attack occurred after death.

We mailed a questionnaire to the wildlife agencies of all states within the range of alligators. The questionnaire requested data on the number of attacks in the state, the period over which these attacks occurred, length and sex of the attacking alligator, age and sex of the victim, and information about the victim's activity prior to the attack.

All states returned the questionnaires. We found 236 recorded cases of alligator attacks on humans going back as early as 1948 and through the end of 1995 (Appendix 1). Two hundred and eighteen (92%) of the recorded attacks occurred in Florida, six (3%) in South Carolina, five (2%) in Georgia, four (2%) in Alabama, two (1%) in Texas, and one (0.4%) in Louisiana (Table 1).

Eighty-four percent of the victims of known sex were males; 16% were females. The average age of the victim was 31.8 (SE = 1.4) and ranged from three to 82 years old (Appendix 1). Twelve percent of the victims were less than 11 years old, 16% were 11–20 years old, and 20% were between 21–30.

Thirty-four percent of the victims were totally immersed in the water (e.g., swimming, floating) when attacked, 17% were partially in the water (e.g., wading), 38% were on shore, 2% in boats, and the location of 9% could not be determined (Appendix 1). Alligators attacked people swimming, snorkeling, or scuba diving 76 times (32% of all attacks); fishing, clamming, and baiting 21 times (9%); and playing golf or retrieving golf balls 24 times (10%). Eight attacks (3%) occurred when the victim was feeding alligators or other animals. In 20% of the attacks, humans made first contact (often inadvertent) by swimming into, jumping on, picking up, displaying, wrestling with, moving, or trying to harvest the alligator that attacked them.

Alligators involved in human attacks ranged in size from 0.3–3.8 m (mean = 2.0 m, SE = 0.06). For 75 attacks, the sex of the alligator was determined; 73% were males and 27% were females.

Eight people (four males, four females) have died in the U.S. from alligator attacks (3% of all attacks)—seven in Florida and one in Georgia. Their ages were 4, 4, 10, 11, 16, 29, 52, and 70. Four of these victims were swimming or snorkeling prior to the attack; three were walking along the shore or wading (these were the three youngest victims); and the activity of one victim is unknown. These statistics exclude seven fatalities in Florida for which it could not be determined if the alligator attack caused the victim's death or if the attack occurred after death.

Alligator attacks increased dramatically in the 1980's and from 1990–1995 (Table 2). For instance, there was only one recorded alligator attack in the 1940's and 1950's, but 78 in the 1980's and 110 from 1990–1995.

Many factors have contributed to the recent increase in the frequency of alligator attacks on humans. With the decline of alligator hunting and poaching due to protective legislation, populations have rebounded and alligators probably have become less wary of humans. Certainly alligators had less to fear from humans during the 1970's and 1980's than before. Since 1970, an increase in human population in Florida and the other southern states has occurred, along with residential development of waterfront property, and a growing popularity of water recreation activities. All of these factors have caused an increase in alligator-human interactions. Part of the recent increase, however, is an artifact that can be attributed to state agencies keeping better records of alligator attacks since 1970 and to a public that presently reports a higher proportion of attacks to government officials than was the case several decades ago.

State wildlife agencies have responded to the expanding alligator populations, threat of alligator attacks, and public concern (Hines and Scheaffer 1977) by implementing alligator manage-

*No information is available about four alligator attacks in Alabama.

ment plans (Hines and Woodward 1980; Taylor et al. 1991). These plans often call for the removal of nuisance alligators and improved public education about alligators and the dangers they pose. Furthermore, states have started harvesting alligators. But, as long as humans and alligators share the same space, some attacks are inevitable.

Acknowledgments.—We thank the following individuals for providing data for their respective states: Amos Cooper (Murphee Wildlife Management Area, Texas), Celeste Gutierrez-Sanders (Florida Game and Fresh Water Fish Commission), Walt Rhodes (South Carolina Department of Natural Resources), Stanley Stewart (Alabama Game and Fish Division), and Fred Todd and George Steale (Georgia Department of Natural Resources).

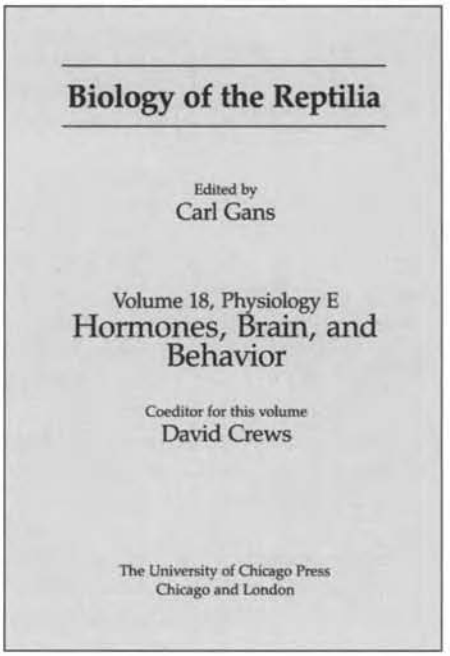
*No information is available on the four alligator attacks in Alabama.

Now Published by the Society for the Study of Amphibians and Reptiles

A series worthy of an honored place in the library of anyone interested in the Reptilia.
—Alfred Sherwood Romer
(*American Scientist*)



A broad, unified treatment of everything concerning the structure and the life of living reptiles.
—Benedetto Lanza (*Scientia*)

There has been no work comparable to this in any language.
—Garth Underwood
(*British Journal of Herpetology*)

BIOLOGY OF THE REPTILIA

THIS CELEBRATED SERIES, NOW EXTENDING TO 18 VOLUMES, HAS BEEN WIDEly acclaimed as the definitive resource on reptilian biology. From the first volume in 1969, the distinguished contributors to this series have included an international group of more than 100 experts in their respective fields. Each volume consists of five to 15 chapters summarizing the state of our knowledge, laying groundwork for future research, and providing an in-depth guide to the relevant literature. All volumes are fully illustrated with photographs, graphs, and extensive tables of information. Several additional volumes are planned. Each volume has both topical and taxonomic indices, and a comprehensive index to the entire series, to be published as the final volume, is in preparation. SSAR is proud to assume responsibility for this classic series and to offer clothbound volumes at affordable prices.

VOLUME 19: TO BE PUBLISHED FALL 1997

Morphology, Volume G: The Visceral Organs. Edited by Carl Gans and Abbot S. Gaunt.

Topics and authors:
The Pulmonary System: *General Overview*, by Steven F. Perry; *Lungs of Snakes*, by Van Wallach; *Pulmonary Function*, by Warren Burggren, Allan Smits, and Tobias Wang.
The Cardiovascular System: *The Heart*, by Anthony Farrell, A. K. Gamperl, and the late E. T. B. Francis; *Cardiac Shunting*, by James Hicks. *The Hepatic System*: *The Liver*, by Fenton Schaffner. *The Spleen*: by Yasukazu Tanaka.

This volume summarizes the major organs situated in the coelomic space, organs that function in metabolism or are involved with endocrine and reproductive activities. As such, it will be of interest to zoologists and herpetologists but also to veterinarians and herpetoculturists. Each chapter includes descriptive morphology combined with discussions of function and of ecological and evolutionary relationships.

Specifications: About 425 pages, 125 figures, indices, clothbound with dustjacket. ISBN 0–916984–42–7. To be published fall 1997.

Some species of lizards form aggregations or groups of individuals in close physical proximity to one another (Burns 1970; Congdon et al. 1979; Cooper et al. 1985; Ruby 1977; Vitt 1974; Worthington and Sabath 1966); however, all of these aggregations were either observed in the winter or in the laboratory. In this note we describe our observations on summer aggregations of *Sceloporus mucronatus mucronatus*.

Sceloporus m. mucronatus (Cope) is a medium to large viviparous phrynosomatid lizard (Frost and Etheridge 1989) that occurs at high elevation in the Mexican states of Hidalgo, Veracruz, Puebla, and México (Smith 1936). It is abundant on rock outcrops and ledges that have numerous crevices that serve as refugia.

Our study site was located in Sierra del Ajusco, México (3400 m elevation), km 19 on the Ajusco-Tianguistence highway (México Highway 892). The site was an open area (ca. 1 ha) with basaltic rocks and lava interspersed with grassy patches (*Festuca amolissima*), and surrounded by a *Pinus hartwegii* forest. We visited the study site sporadically from 27 January 1991 to 30 May 1995. During each visit, we surveyed rock crevices for groups of lizards. For each aggregation, we recorded the number of lizards and their sex. Sex was determined definitively because males have bright blue ventral patches, whereas females have diffuse blue ventral patches. Means are given ± 1 SE.

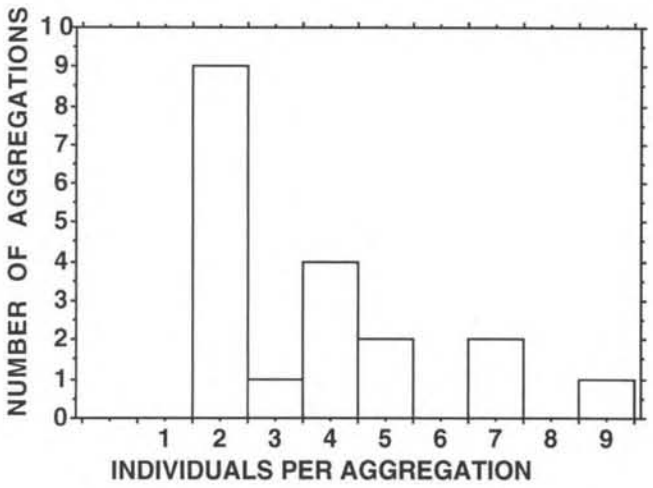

FIG. 1. The number of individuals in aggregations of *Sceloporus mucronatus* from the Sierra del Ajusco, México. Total number of aggregations is 19.

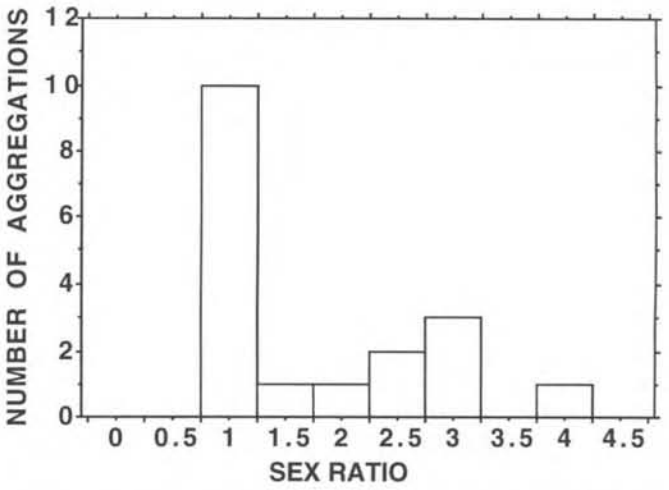

FIG. 2. The sex ratios of aggregations of *Sceloporus mucronatus* from the Sierra del Ajusco, México. The ratio is females:males. Total number of aggregations is 18.

We observed a total of 19 aggregations. Eighteen of these aggregations involved adults (individuals with SVL > 60 mm; sexual maturity occurs around 60 mm SVL; Mendez de la Cruz et al. 1988), and one was a pair of juvenile males. The number of individuals in an aggregation ranged from 2 to 9, with a mean of 3.7 ± 0.5 individuals per aggregation, with 2 being the mode (Fig. 1). The sex ratio of the aggregations ranged from 1 male: 1 female to 1 male: 4 females (Fig. 2). The mean sex ratio was 1.8 ± 0.2 females per male (N = 18). The sexes of all individuals in the 9 lizard aggregation could not be determined because all individuals could not be caught. Groups of two individuals were the mode, and these were always composed of a male and a female. Aggregations were found throughout the day from 1000 h to 1630 h. The majority of aggregations were seen on cloudy days (16), whereas three were seen on sunny days. Aggregations were seen during the summer (May–August) and in the winter (January).

At this time, we do not have the necessary information to determine the reasons for aggregation behavior in this population; however, we think two alternative, but not necessarily mutually exclusive, explanations deserve further evaluation. First, the aggregations may serve a social function or may reflect mating aggregations, suggested by the observation that all pairs were male-female pairs. Although we did not observe mating behavior, it has been reported to occur in the month of June (Mendez de la Cruz et al. 1988), and all recorded males were brightly colored, suggesting mating was taking place in the sampling period. Also, there appears to be a shift in aggregation behavior with age: older and larger individuals aggregate whereas younger and smaller individuals do not. The second explanation is that these aggregations may serve a thermoregulatory function: individuals aggregated to help maintain body temperature. There are several reports of winter aggregation in another high altitude, viviparous *Sceloporus*, *S. jarrovi* (Burns 1970; Congdon et al. 1979; Ruby 1977), and in *Urosaurus ornatus* (Vitt 1974; Worthington and Sabath 1966), all of which may be attributed to some extent to thermoregulatory considerations. The evidence for a thermoregulatory function of aggregation in *S. mucronatus* is weak compared to that for a social function. Aggregations were observed through-

out the day, and although they were primarily observed on cloudy days, aggregations also were seen on sunny days. Finally, if there was a thermoregulatory basis for aggregation one would expect to see juveniles together, but only one such grouping of juveniles was seen.

Acknowledgments.—We thank N. Zucker for her comments on an earlier version of this note. We appreciate support provided by the School of Biological Sciences at the University of Nebraska-Lincoln and the Department of Forestry and Agriculture in México.

Putative Anting Behavior in Wood Turtles

"Anting behavior," the use of ants by vertebrates to remove epibionts, has been investigated primarily in birds. Despite numerous observations of this peculiar behavior (reviewed by Potter 1970), its exact function remains unclear. Suggested explanations for anting behavior include removal of ectoparasites (Groskin 1950), soothing of skin irritation caused by molting (Potter 1970), and inhibition of fungal and bacterial growth (Ehrlich et al. 1986).

Recently, observations of associations between ants and vertebrates have been expanded to include primates (Longino 1984) and reptiles, including turtles (Burke et al. 1993; Riley et al. 1985). Burke et al. (1993) found that the leech *Placobdella parasitica* was absent from snapping turtles (*Chelydra serpentina*) that had nested on mounds of the carpenter ant (*Formica obscuriventris*) in southeastern Michigan. All snapping turtles that did not visit mounds were parasitized by leeches, which commonly occur on that species (Brooks et al. 1990).

We found evidence of an association between wood turtles (*Clemmys insculpta*) and the ant *Formica* sp. (Fusca species group) during a study of movement patterns in wood turtles (McCurdy 1995) at the Saint Mary's River in Nova Scotia, Canada. Turtles were captured and radiotagged by searching the banks of the river in June, 1994. A subset of the radiotagged animals was then fitted with thread spools for trailing.

On 11 July 1994, Turtle 1 (a 20 year old male, based on plastron annuli counts; carapace length 211.5 mm; mass 1.31 kg) was thread- and radio-trailed 250 m upstream and 50 m inland to an ant mound. Here, he was found resting on top of the mound with the thread spool attached and still trailing. Ants covered the turtle for about 20 min, after which the turtle moved off the mound and walked 8 m northeast. He subsequently backtracked 6 m to the ant mound and returned to the river.

On 21 July, Turtle 2 (a 21 year old male; carapace length 209.0 mm; mass 1.05 kg) was tracked to a wooded hill northwest of the ant mound. His thread trail led directly over the same ant mound that Turtle 1 had visited. In addition, Turtle 2's trail back to the river followed the exact travel path used by Turtle 1 when the latter returned from the mound to the river. This was the only observation of two individuals using a common travel path during our study.

Ants were observed crawling over the legs, carapace and head of Turtle 1 during the observation of 11 July. While on the ant mound, Turtle 1 made no effort to rid himself of ants, consume them, or move away from the mound. Although wood turtles are opportunistic foragers, invertebrates comprise only a minor portion of their diet (Strang 1983). At the Saint Mary's site, wood turtles were observed eating a variety of food items including fungi, green leaves, fruit, and algae; however, ant-eating was never observed here or at another site in Nova Scotia (McCurdy and Herman, unpubl. data).

The ants found in the mound are from the same group involved in anting associations with birds and are thus good candidates for demonstrating a mutualism with wood turtles. Ants in the Fusca group have often been observed in anting associations with robins (*Turdus migratorius*; Nichols 1943), starlings (*Sturnus vulgaris*; Brackbill 1948), catbirds (*Dumetella carolinensis*; Brackbill 1948), wood thrushes (*Hylocichla mustelina*; Groskin 1950) and blue jays (*Cyanocitta cristata*; Potter 1970).

The function of anting behavior in wood turtles is not known, but it is instructive to compare this species with observations on snapping turtles. Ants may eat leeches from wood turtles, as suggested by Burke et al. (1993) for snapping turtles. Although leeches were not observed to be removed during the 11 July observation of Turtle 1, wood turtles at the Saint Mary's River were often parasitized by *P. parasitica*, and many individuals had more than 50 leeches at first capture. Over 90% of wood turtles in a New Jersey population captured during spring and fall carried leeches (Farrell and Graham 1991).

There are several other methods that turtles may use to remove leeches including associations with birds and fish, and basking. Map turtles (*Graptemys geographica, G. ouachitensis*, and *G. pseudogeographica*) and common grackles (*Quiscalus quiscula*) are involved in a mutualistic relationship in which *P. parasitica* are removed by the birds (Vogt 1979). Kaufmann (1991) observed wood turtles apparently cleaned by blacknose dace (*Rhinicthys atratulus*). These types of relationships were not observed during our study; however, all leech-removal associations between turtles and other vertebrates probably are isolated and difficult to observe.

Basking or drying (Boyer 1965) are unlikely to be effective in removing leeches from wood turtles, which are active at lower temperatures and spend less time basking than other turtle species (Ernst 1986; D. McCurdy, pers. obs.). As well, even though wood turtles are primarily terrestrial in summer, *P. parasitica* are able to survive long-term desiccation (Hall 1922).

Even if anting does not reduce leech loads, the behavior could benefit wood turtles in other ways. The formic acid sprayed by ants can be an effective deterrent of fungal or bacterial parasites (Ehrlich et al. 1986). The preference of wood turtles for humid microenvironments, which promote fungal and bacterial growth, provides another putative selection pressure for anting. Clearly, the relationship between wood turtles and *Formica* sp. requires further study to better understand the evolution of anting behavior in vertebrates.

Acknowledgments.—We thank Tom Alloway at Erindale College, University of Toronto, for identifying the ants. Logistical and technical support was provided by Neil Meister, David McCurdy, Iris McCurdy, and the Nova Scotia Department of Natural Resources (Stillwater, Nova Scotia). Mark Forbes and Lorraine Standing provided comments on the manuscript. Funding for wood turtle research was provided by a grant from the Natural Sciences and Engineering and Research Council of Canada.

No data exist concerning growth of subadult alligator snapping turtles (*Macroclemys temminckii*) in a natural environment. Growth is thought to begin in March and continue through July, but seems to slow substantially after 15 years of age (Dobie 1971). According to Drummond and Gordon (1979), captive turtles grew 1 mm in carapace length within the first 11–14 days after hatching and had increased 2.6 g in weight after the first 47–50 days. Allen and Neill (1950) reported carapace lengths of 84 mm and 90 mm and carapace widths of 75 mm for two turtles after five years in captivity. Other researchers have reported *M. temminckii* gaining 500 to 900 g per year (N. H. Douglas, pers. comm.). Although growth data can be collected from captive *M. temminckii*, this is unlikely to be representative of growth in a natural environment. Errors in conservation and management decisions may occur in the absence of accurate growth data for wild populations, particularly if growth time to sexual maturity is underestimated. *Macroclemys temminckii* is singularly important in that this species is classified as a restricted, threatened, or endangered species in most states (Ernst et al. 1994; Pritchard 1989).

We report one year growth data collected from 12 subadult *M. temminckii* in a Louisiana bayou (Harrel et al. 1996). The study site was Bayou Desiard, a slow-flowing bayou located 10 km north of Monroe, Ouachita Parish, Louisiana, USA. Turtles were captured using baited hoopnets, and measured to ensure that they were within our desired size range (Harrel et al. 1996). A 66 g radio transmitter was attached to each turtle's carapace and all were released (within 2 h) at the capture site. The 12 turtles used in the study were recaptured after one year (mean = 371 ± 1.8 days) and re-measured. The turtles were not captured at any other time, appeared healthy, and incurred no mortality. The sex of the turtles was determined laparoscopically at the conclusion of the telemetry study (Wood et al. 1983).

The following straight-line measurements were taken with a Mantax 24-inch steel (vernier) caliper to the nearest 0.1 inch: carapace length (CL) and width (CW), plastron length (PL) and width (PW), head length (HL), and pre-cloacal tail length. Carapace length was measured from the anterior portion of the nuchal to the posterior marginal edge, CW at the widest point (generally between the eighth and ninth marginals), PL along the mid-plastral seam from the anterior portion of the gular to the posterior portion of the anals, PW across the abdominals between the plastron/carapace seam, and HL from anterior to the bony premaxilla to the posterior bony portion of the supraoccipital. The pre-cloa-

TABLE 1. One year's (1992–1993) growth (cm, kg, %) for 12 subadult (3 male, 9 female) *Macroclemys temminckii* in a Louisiana Bayou.

Days of Growth	Carapace Length	Carapace Width	Plastron Length	Plastron Width	Head Length	Weight
			Males (N = 3)

Range (365–383)	(0.1–2.6)	(0.6–2.0)	(0.5–1.8)	(0.5–3.3)	(0.0–0.8)	(0.00–0.8)

cal length (recapture only) was measured from the posterior edge of plastron to the anterior edge of the cloaca. Turtles were weighed to the nearest 0.1 lb on a Hanson 860 scale. English units were converted to metric. Three subadult males had the following mean measurements at time of capture: CL = 26.3 ± 0.23 cm; CW = 22.0 ± 0.31 cm; PL = 19.6 ± 0.30 cm; PW = 17.8 ± 0.81 cm; HL = 9.1 ± 0.00 cm; and weight = 4.2 ± 0.27 kg. The nine females had the following mean measurements at the time of capture: CL = 24.8 ± 0.48 cm; CW = 21.2 ± 0.49 cm; PL = 18.5 ± 0.35 cm; PW = 17.9 ± 0.65 cm; HL = 8.5 ± 0.21 cm; and weight = 3.7 ± 1.23 kg.

Mann-Whitney U-test showed males had significantly longer precloacal lengths (mean = 7.5 ± 0.10 cm) than did females (mean = 5.6 ± 0.08 cm), (P = 0.014, U = 27.000). The turtles' mean growth was small (Table 1). The Mann-Whitney U-test showed no significant difference in growth between male and female subadults in any measurement (P > 0.275, U ≤ 20.000).

Macroclemys temminckii is the largest North American freshwater turtle, and thus its growth rate may not be comparable to those of other turtle species. Dobie (1971) considered alligator snapping turtles to be sexually mature at carapace length = 37.0 cm for males and 33.0 cm for females. Using our one year's mean growth of 1.37 cm and a current carapace length of 27.67 cm, these male turtles would require approximatly seven more years to reach sexual maturity. Female mean carapace length is currently 26.11 cm and with a growth rate of 1.31 cm per year would require approximately five more years to reach sexual maturity. Our predictions assume a constant rate of growth. Obviously, researchers would need to follow growth over several years to test this hypothesis. Only one turtle lost weight during the study. Weight gain (or loss) may be dependent on several factors including time since last meal, time of year, time since defecation, and general quality of health. We concur with other authors that weight is not as reliable an indicator of turtle growth as shell growth (Bjorndal and Bolten 1988).

We anticipated more growth than was recorded for these subadult *M. temminckii* considering that growth was reported to slow substantially after 15 years (Dobie 1971). Our data support the concept that this species is slow growing and that it may take more than a decade to reach sexual maturity. In addition, external morphological differences (longer pre-cloacal lengths) between males and females are evident early in their ontogenetic development and may prove useful for distinguishing sexes without using laparoscopical methods. Turtles used in this study were tagged and released at their recapture location, and future recapture measurement of these turtles will be reported to determine if the growth rates have changed.

Acknowledgments.—We thank the Fur and Refuge Division of Louisiana Department of Wildlife and Fisheries for making this study possible. We also thank Sherry Harrel, Tony Trichel, Toby Trichel, Steven George, Anthony Newman, and Edwin Ritter for their assistance. Author Liles and Chris Holt deserve thanks for their help in laproscopy techniques. We thank Jeffery Lovich, William Gutzke, and Anne-Marie Murphy for comments and suggestions. We thank Neil H. Douglas for providing excellent holding accommodations at Northeast Louisiana University's Turtle Research Facility. A special thanks goes to Keith Cascio for his help during recapture efforts.

Aggregation behavior in snakes has been attributed to prey abundance, communal hibernation, mating, and egg-laying (Gregory et al. 1987). Although aggregation for communal egg laying is known for several species (e.g., *Demansia psammophis* in Australia, Covacevich and Limpus 1972; *Leptotyphlops dulcis* in Kansas, Hibbard 1964), aggregation of gravid females of live-bearing species is comparatively rare (Gregory 1975; Reichenbach 1983; Rossman et al. 1996). Furthermore, in the Middle East there are no reports of aggregation behavior for any species of snake. In this note, we report aggregations of *Coluber rubriceps* (Venzmer 1919) and *Typhlops vermicularis* (Merrem 1820).

Aggregation of Coluber rubriceps.—In July 1993, the Chief of Agriculture in the Ma'an District, Jordan, brought to our attention an "outbreak" of snakes in Dlaghah village (35 km W Ma'an). Upon visiting the area (16 July 1993) we found ca. 600 newly hatched snakes and more than 200 unhatched eggs under a brick staircase leading to a four-year old house. The stairway was 2 m wide and 60 cm high, surrounded by cement pavement 1 m wide that surrounds the house. The pavement is wide, made of small rocks covered by cement, with many cracks on the sides. An irrigation canal is located at the back of the house. The house is surrounded by olive, fig, and grape trees.

Subsequently, in June 1994, another "outbreak" was reported from the same staircase in Dlaghah. About 350 gravid females were found. Only a few eggs were found clumped together. We collected a series of 35 gravid females, which were measured, weighed, and then dissected to determine number of eggs. The mean number of eggs per female was 4.8 (N = 35; SD = 1.43) and their mean weight was 1.85 g (N = 50; SD = 0.39). Mean total length of the females was 706.1 mm (N = 35; SD = 64.14), snout-vent length 510.5 mm (N = 35; SD = 46.45), with a mean weight of 37.78 g (N = 35; SD = 10.2).

Aggregation of Typhlops vermicularis.—In March 1991, a student brought 23 specimens of the blind snake, *T. vermicularis*, from Irbid, Jordan. The snakes were found under a stone in the garden of a house. Red soil (terra rosa) is the prevalent soil type in northern Jordan. No eggs were collected or seen at the site. Mean total length for the specimens is 152.6 mm (N = 23; SD = 29.4).

Discussion.—Despite several studies on the snakes of Jordan (Amr et al. 1994; Disi 1985; Disi et al. 1988; El-Oran et al. 1994), none of these reports mentioned aggregation behavior among any of the 34 snake species found in Jordan. *Coluber rubriceps* is a common species in southern Jordan, where it inhabits rocky and humid terrain. The blind snake, *Typhlops vermicularis*, is common in northern Jordan, where it prefers areas of moist soil.

The aggregations of *Coluber rubriceps* fall within the category of communal egg-laying. In the first "outbreak," newly hatched individuals were seen, while gravid females were encountered on the second occasion. This suggests that egg-laying takes place in late June–early July. Individuals of this species chose the same site for egg-laying in two successive years. Perhaps communal oviposition and female aggregation is mediated by chemical senses (Plummer 1981). Selecting the same site over a period of two years could be explained on the basis of "habitat conditioning" in which snakes use a particular site for aggregation even though alternative or similar sites are available (Burghardt 1983). Indeed, several old, ruined houses made of mud and stones are within 500 m of this particular house and seem to be suitable as a hiding place for snakes; however, after inspection of them, no snakes were found. Nest site selection is influenced by the immediate surroundings. In this study, the site is well protected, humid, and dark, with easy access for individual snakes which may be attracted by conspecific chemical cues. Covacevich and Limpus (1972) reported similar observations of nest site selection for the yellow-faced whip snake, *Demansia psammophis*. We suspect that gravid females gain an advantage against predators, in that a predator will not be able to take all individuals at the same time, thus allowing others to escape (Shine 1979). Predators of *C. rubriceps* include raptors and small carnivores such as the mongoose, *Herpestes ichneumon*.

We attribute the aggregation of *Typhlops vermicularis* to either mating or moisture conservation behavior. The latter was noted by Thomas (1965) among 19 specimens of *Typhlops richardi* found under a rotting *Cocos* log. *Typhlops vermicularis* is subterranean in dry regions and open habitats. Aggregation of several individuals may be directed by chemical cues. The time of year at which specimens were collected (March) is relatively cool and humid. This suggests that mating was the main function for blind snake aggregation on this occasion.

Acknowledgments.—The authors thank Lubna Ammareen for her technical assistance and Ahmed Abo Akala, Chief of Agriculture, Ma'an District, for his help. This work was supported by Mutah University. We thank Kraig Adler, Cornell University, for his editorial help on the manuscript.

Digital Webbing Formulae for Anurans: A Refinement

JAY M. SAVAGE

In 1967 we proposed a system of notation to describe the presence and extent of finger and toe webs in frogs and toads. The degree of webbing was expressed in terms of how many segments of the digits (phalanges), hand (distal metacarpal), or foot (distal metatarsal) are free of webbing. Myers and Duellman (1983) modified the original scheme to more accurately reflect conditions in anurans having the segment containing the terminal phalange expanded into a complex scansorial disk.

In the currently used system each finger and toe is represented by a Roman numeral and the extent of the webbing between the digits by an Arabic numeral. If the web extends to the tip of the digit, it is recorded as an O. If it extends to the base of the terminal phalange, the notation would be 1, if two phalanges are free of the web, it would be 2, etc. Since the division of the fingers and toes continues between the metacarpals and metatarsals, the webbing formula refers to the number of segments and/or fractions thereof free from the web. A typical webbing formula for a hand would be: I 2 - 2 II 2 - 3 III $2^{1}/_{2}$ 2 IV; for a foot I $1^{1}/_{2}$ - 2 II 1 - 2^{-} III 1 - $1^{1}/_{2}$ IV 2^{+} - IV. Superscripts (+ or –) indicate that the web reaches just proximal or distal to the subarticular tubercle or terminal distal joint (e.g., 2^{+} means 2 segments plus are free of the web).

Myers and Duellman (1983) used "1" to indicate that the terminal disk or entire terminal segment is free of the web. However, in many forms having digital disks, these two conditions are not identical. The situation is further complicated in those taxa having an intercalary cartilage between the distal and penultimate phalanges. For these reasons we propose that when the web, in disked forms, extends beyond the joint between the penultimate and distal phalanges toward or to the tip of the digit, it be scored as 3/4, 2/3, 1/2, 1/3, 1/4, or 0. In forms having an intercalary cartilage, we recommend that as a convention, it be considered part of the distal phalange and that the same type of notation as described above be used for formulae where the web extends beyond the 2nd phalange-intercalary cartilage joint toward or to the tip of the digit.

Platymantis reticulatus Brown, Brown, and Alcala (1997:416) is a primary homonym of *Platymantis reticulatus* Zhao and Li (1984) (now *Micrixalus reticulatus* or *Ingerana reticulata*; see Zhao and Adler 1993; Dubois 1992). Under the provisions of Article 60c of the International Code of Zoological Nomenclature (Anon. 1985) we replace the name *Platymantis reticulatus* Brown, Brown, and Alcala, 1986, with *Platymantis isarog* (*nomen novum*). The species name *isarog* is a noun in apposition referring to the type locality of this species (Mt. Isarog (1200–1300 m), Camarines Peninsula, southeastern Luzon Island, Philippines).

In response to our need to sample tiger salamanders (*Ambystoma tigrinum*) in diverse wetland habitats of the Prairie Pothole Region (PPR), we designed a funnel trap that overcomes many of the problems associated with other sampling methods (Berger 1984; Heyer 1976, 1979; Shaffer et al. 1994). We evaluated our trap in 17 seasonal and semi-permanent wetlands at the Cottonwood Lake Study Area (CLSA) in Stutsman County, North Dakota, USA; wetlands of the CLSA are typical of depressional wetlands found elsewhere in the PPR.

Our funnel trap has a welded rectangular frame constructed of 0.63 cm diameter steel rod covered with 0.32 cm mesh galvanized screen (Figs. 1 and 2). We constructed a 5 cm wide funnel opening that is raised 7.62 cm above trap bottom on one side of the trap, and attached a hinged mesh lid to the top of each trap. To firmly seat the trap in the substrate, we extended four steel rods 30 cm beyond the bottom of the trap; these legs can be omitted and weights may be substituted and used as anchors in wetlands with rocky substrates. An additional feature of our trap is a 200 cm drift fence that directs free-swimming salamanders to the opening of the trap. The drift fence is constructed of 0.32 cm mesh nylon, 91.4 cm wide, with the ends folded over to form end loops. We attached the drift fence to the trap by inserting a threaded steel rod through a small opening at the top of the trap and through the end loop in the drift fence. We then screwed the rod into a 0.63 cm nut welded to the bottom of the funnel opening. The opposite end of the drift fence was supported by inserting a length of 2.54 cm PVC pipe through the end loop and into the substrate. Lead weights attached to the bottom edge of the drift fence maximized contact with the substrate. Floats attached to the top of the submerged portion of the drift fence maintained its vertical orientation. Where water depths exceeded 91 cm we increased the height of the fence by adding a second length of 0.32 cm mesh nylon.

These traps have proven effective in all wetland vegetative zones and in water depths ranging from 10 cm to over 2 m. During each

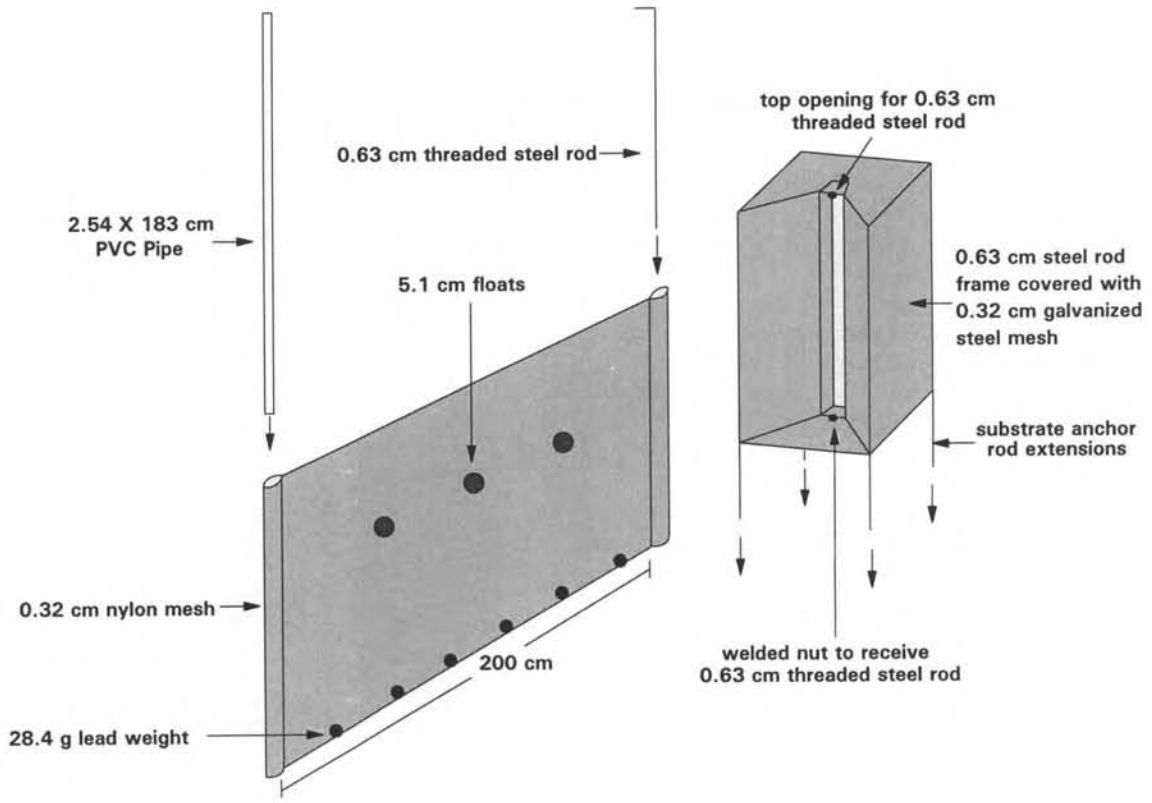

FIG. 1. A funnel trap for sampling amphibian larvae in wetlands. Overall height of trap and drift fence should be determined by the maximum depth anticipated in the wetland being sampled. The trap should be set 10 cm above the water surface to allow sampling of the entire water column while simultaneously providing oxygen to captured animals.

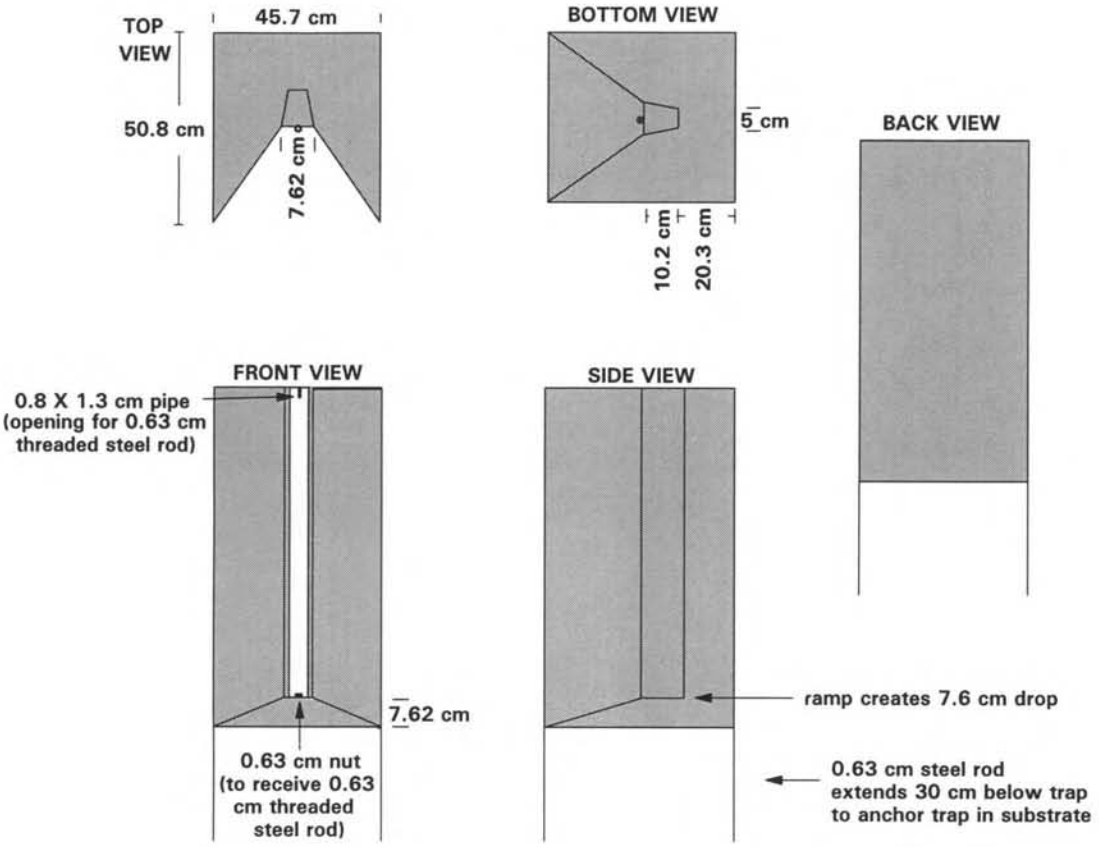

FIG. 2. Construction detail of a funnel trap designed to sample amphibian larvae in wetlands.

of three periods (18–29 July, 1–12 and 15–26 August) in 1994, and concurrent with our funnel trap sampling, we sampled five randomly selected semi-permanent wetlands with minnow traps (0.3 x 1.0 m), seines (4.0 x 1.3 m, 0.6 cm mesh), and dipnets (22.0 x 47.5 cm). Although we were able to deploy minnow traps (10 per wetland) in all five wetlands, our funnel traps (10 per wetland) captured more tiger salamanders (mean = 3.70/trap/24 h; N = 150; SD = 7.60) with less variance than the minnow traps (mean = 0.34/trap/24 h; N = 150; SD = 1.34). Seining and dipnetting were not satisfactory sampling techniques because of submergent and emergent vegetation, which severely limit the use of seines and dipnets as a quantitative tool in well-vegetated depressional wetlands of the PPR.

Our funnel traps cost ca. $45 per trap for materials; minnow traps are commercially available for $13.50 per trap. Labor to install funnel and minnow traps is similar. While the higher cost of our trap may limit its use to some extent, greater capture rate combined with the ability to sample the entire water column with reduced mortality may justify these higher costs. When sampling rare taxa our trap may detect populations other sampling techniques overlook.

A Cage for Evaluation of *In Situ* Water Quality Using Frog Eggs and Tadpoles

MEGAN L. HARRIS

and

JAMES P. BOGART

Department of Zoology, University of Guelph
Guelph, Ontario, Canada N1G 2W1
e-mail (MLH): mharris@tox.uoguelph.ca

Evaluation of the early life history of larval amphibians occasionally has been accomplished with the use of field enclosures (Kupferberg et al. 1994; Tejedo and Reques 1994). The effect of a modified environment or of reduced water quality on embryo–larval development have become issues of concern (Vial and Saylor 1993). Several investigators have tested for compromised development by caging tadpoles in affected environments (Clark and Hall 1985; Cooke 1981; Materna et al. 1995), yet only sketchy descriptions of cage designs exist. Eggs and larvae of amphibians require specific levels of dissolved oxygen, temperature, and light intensity (Duellman and Trueb 1986), and this must be considered when designing holding cages. The following is the cage design used successfully for short-term studies of the early development of temperate ranid frogs (Harris 1996).

The cage has two components to accomodate the physiological needs of both embryos and tadpoles. The outer component is a cylinder (20 cm depth, 15 cm diameter) made from rigid 500 µm white Nitex nylon (Tetko Inc., New York) with 39% open area and 32 mesh counts/inch (Fig. 1). The cylinder is created by stitching together, with nylon thread, the overlapping ends of a 20 x 50 cm Nitex rectangle, and adding a Nitex bottom. Mesh edges are melted lightly with a soldering iron to prevent fraying, and inert silicone is placed along nylon edges to ensure that there are no pockets of material into which a swimming tadpole could enter. A removable Nitex lid is attached to the cage by stitching a 12 mm wide strip of velcro to the top of the cylinder with nylon thread and then attaching the opposite side of the velcro strip to the lid. The Nitex outer cage is strong enough to maintain its shape without buckling or folding inwards, which guarantees that a consistent volume of open, oxygenated water is available to swimming tadpoles. The inner component is a shallow kitchen strainer (5 cm depth, 10 cm diameter, plastic mesh) with the handle cut away. The lightweight plastic, coupled with a thin layer of flexible foam glued to the rim, allows the strainer to float at the water line inside the larger cylinder. Cages are anchored with the top sitting a few centimeters above the water line, and maintained by slipping 0.6 cm diameter wooden dowels through plastic rings (19 mm diameter, available in any craft/hobby store) sewn to the cage sides, and tapping the dowels into the pond bottom. Eggs separated into small clumps to avoid crowding have their protective jelly coat reduced and can no longer stay afloat; these eggs are maintained in the shallow inner basket, up in the oxygen-rich water zone at the surface until they hatch. Upon hatching, tadpoles are tipped gently into the much larger outer cage and a feeding routine initiated.

This design is considered appropriate for early life stage development studies of most temperate frog species and some salamander species. Mesh size is sufficiently small to preclude virtually all aquatic predators, but large enough to allow sufficient water movement, even with limited algal fouling. The cylindrical shape prevents entrapment in corners, and the cage size may be increased easily to accommodate extended study periods. In aquatic environments where large fluctuations in water level are common, or where there is a current, it might be useful to replace the dowel anchor system with a weighted anchor, rope, and single dowel to maintain cage position. Flotation may be achieved by attaching a strip of soft, flexible foam (like self-adhesive weather stripping) around the outside of the cage about 3/4 of the distance above cage bottom. Stitching this foam to the cage is recommended, but non-toxic glue may also work.

Consideration should be given to the natural placement of egg masses for each study species when placing cages in pond, ditch,

or stream. For species that naturally receive reduced light or dissolved oxygen, the use of the inner floating basket may not be necessary. In most cases, the cages should be placed near shore, but out of the reach of wader-less people and curious animals (raccoons, dogs). The Nitex nylon should be white or pale to allow light penetration and prevent overheating.

Although there may be some temptation to skimp on materials (total cost of the described cage was US $7.38), cheaper types of screening often do not maintain the same structural integrity, and produce some mortality via entrapment of tadpoles. Metallic screening may have an associated toxicity to embryos and larvae (Harfenist et al. 1989).

The eggs and tadpoles of northern leopard frogs (*Rana pipiens*) and green frogs (*Rana clamitans*) were maintained in these cages in small permanent ponds in Ontario, Canada, and survival, deformity, and growth responses of the two species were evaluated in differing water quality for two or three weeks (Harris 1996). Studies were initiated once fertilized eggs reached Gosner Stage 8 (1960; late cleavage) and continued until tadpoles developed to Stage 25 (complete development of spiracle), at least two weeks. Survival in cages held in reference ponds was typically 90–100%. Occasionally, however, survival fell to 60–87%. In such cases, initial fertilization success was very poor (<70%), and the poor survival was attributed to the eggs being of inferior quality. With densities of ten individuals per cage, the developmental complications generally triggered by crowding (Rose 1960) were not witnessed. Habitability of aquatic sites to early life stages of amphibians may be assessed using this controlled cage environment.

Acknowledgments.—We thank Leslie Rye for the use of her sewing machine and for assistance in cage construction, Andrew Magloire, Jim McLister, and Lisa Peters for providing valuable assistance in completing the cages, and Christine Bishop and Mike van den Heuvel for reviewing this manuscript. Thanks also to Christine for providing an earlier prototype, and sharing the limitations of that design with us; her recommendations were considered in our cage design. This work was funded by an NSERC operating grant, and by a World Wildlife Toxicology Fund grant.

Efficacy of Capture Methods for a Low Density Population of *Phrynosoma cornutum*

W. SCOTT FAIR
and
SCOTT E. HENKE
Caesar Kleberg Wildlife Research Institute, Texas A&M University-Kingsville
Box 218, Kingsville, Texas 78363, USA
e-mail (SEH): Kfseh00@tamuk.edu

Studies concerning *Phrynosoma cornutum* note that specimens are handled, but often neglect to describe the method of capture (Jameson and Flury 1949; Milstead et al. 1950; Munger 1984a, b, c; Sherbrooke 1990). Several researchers mention that incidental sighting and capture by hand was their collection method (Ballinger 1974; Donaldson et al. 1994; Whitford and Bryant 1979). Discussion of capture methods might be unimportant in areas with scant vegetation and relatively high lizard abundance, but areas with greater vegetation cover and lower densities of lizards could require extensive search time. Reptiles have been captured with direct search methods such as road cruising and systematic searches and trapping methods such as pitfall traps and funnel traps (Jones 1986); however, to our knowledge, no assessment of capture methods has been conducted for horned lizards. This study examines the efficacy of these collection methods for a low density population of *P. cornutum* and discusses the advantages and limitations of each method.

The study was conducted from March–October 1994 on the Marvin and Marie Bomer Wildlife Management Area (BWMA), an experimental wildlife management area operated by the Department of Animal and Wildlife Sciences of Texas A&M University-Kingsville, and on the adjoining Pena Ranch. The study area consisted of 58.4 ha of mixed mesquite (*Prosopis glandulosa*) shrubland and prairie grassland located 19.3 km south of Benavides in Duval County, Texas, USA.

Collection methods of *P. cornutum* included pitfall traps, funnel traps, road cruising, and systematic searches. Total capture time (man-hours) for each method was recorded monthly from April–October on ten 1-ha study plots.

A modified trap array (Jones 1986) was used for pitfall and funnel trapping. Three arrays were placed randomly in each of the 10 study plots. Each array contained three 7.6 m by 0.45 m drift fences and four 18.9 L buckets. Drift fences within each array were placed at approximately 120° angles. Buckets were located at the end of drift fences and the three fences converged on a central bucket. Buckets were buried with the top of the bucket flush with the soil surface. The drift fencing was buried 15 cm and vertically supported with wooden stakes. Ends of the drift fencing overlapped the buckets by 5 cm. A 30 cm path was cleared on each side of the drift fencing to exclude any obstructions for the lizards as they travelled along the fencing. Buckets had an elevated cover and contained approximately 3 cm of sandy soil. Buckets were sealed with lids when not in use.

Six funnel traps were placed randomly on the three arrays within a study plot each month. Traps were placed at the center of an array wing. A funnel trap consisted of hardware cloth (bright aluminum replacement screening, 1 mm mesh) rolled to form a 91

cm long and 18 cm diameter cylinder and stapled closed at one end. The open end was fitted with an inverted funnel made of hardware cloth and the two pieces were stapled together (Jones 1986). The funnel contained a 5 cm diameter oval opening. Funnel traps were covered with plywood measuring approximately 30.5 x 30.5 x 0.6 cm to shade captured animals from direct sunlight. Funnel traps were collected when not in use.

Pitfall and funnel trappings were conducted for five consecutive days each month from April to October. The traps remained open 24 h and were checked once a day between 0730 and 1000 h. Captured lizards were recorded and captures per unit effort were computed. Trapping effort was calculated as the hours *P. cornutum* were active each day multiplied by the number of trapping days. Active times for lizards were determined from tracking horned lizards with radiotelemetry in a concurrent study (Fair 1995).

Systematic searches were conducted twice per month from April to October on each of the 10 study plots. Searches were conducted by groups of 14–19 people walking in an evenly spaced line through the study plots looking for *P. cornutum*. Total lizard captures and total man-hours consumed were recorded for each study plot.

Road cruising consisted of one observer driving a truck around the perimeter of the study plots at 16 kph looking for *P. cornutum*. The number of *P. cornutum* sighted and captured within each study plot and on associated roads during each month and the total search time for each study plot during each month was recorded.

TABLE 1. Number of *P. cornutum* collected monthly, total effort (h), and total captures per effort hour for four capture methods on the Bomer Wildlife Management Area in Duval County, Texas, during 1994.

Month	Pitfall Traps	Funnel Traps	Systematic Searches	Road Cruising	Total Captures by Month
Apr	2	0	1	0	3
May	1	1	1	0	3
Jun	1	0	3	1	5
Jul	3	3	3	0	9
Aug	0	0	0	0	0
Sep	0	1	4	1	6
Oct	0	0	0	0	0
Total captures by method	7	5	12	2	26
Total effort (h)	470.00	470.00	223.81	3.89	1167.70
Total captures per unit effort	0.015	0.011	0.054	0.526	0.022

The distribution of captures per unit effort was tested to verify normality with the Shapiro-Wilk test (PROC UNIVARIATE procedure, SAS Inst. Inc. 1989). A completely randomized 1-way analysis of variance (PROC GLM procedure, SAS Inst. Inc. 1989) was used to test the effect of capture methods on lizard captures per effort hour. A priori orthogonal contrasts were used to test for differences between trap types (funnel vs. pitfall), search types (systematic searches vs. road cruising), and capture methods (trapping vs. searching). Sex ratios were analyzed by chi-square analysis to determine if they deviated from a 1:1 relationship for the capture methods. Juvenile:adult ratios for each capture method were analyzed by chi-square analysis to determine if they deviated from the observed ratio for all methods. Lizards were considered adults at snout–vent lengths ≥ 68 mm (Ballinger 1974). Yates correction for continuity was used in the chi-square analyses because the test criteria had a single degree of freedom. All tests were considered significant at the 0.05 alpha level.

Twenty-six *P. cornutum* (16 adults, 10 juveniles; 11 M, 11F) were caught using the four capture methods (Table 1). Four hatchlings were not sexed. July was the most successful month, resulting in nine captures from all the methods. July also was the most successful collecting month for pitfall and funnel trapping, each yielding three captures. Systematic searches captured four lizards in September, and three lizards in both June and July. However, no difference in the captures per unit effort was found ($F = 0.85$; df = 3, 24; MSE = 60.15; $P = 0.4799$) between the four capture methods (Table 1).

Pitfall and funnel trapping required the same effort and yielded seven and five *P. cornutum* captures, respectively. A priori contrasts yielded no difference ($P = 0.6745$) between the trap types. However, a trend was observed ($P = 0.0753$) between the search types. Road cruising yielded a higher mean of captures per effort hour than systematic searches. A trend also was noted ($P < 0.0913$) between the capture methods. Searching methods resulted in a higher mean rate of captures per effort hour than trapping methods.

Sex ratios did not deviate from a 1:1 relationship for pitfall trapping (3 M; 2 F; $c^2 = 0.000$; df = 1; $P = 1.0000$), funnel trapping (2 M; 2 F; $c^2 = 0.250$; df = 1; $P = 0.6452$), systematic searching (6 M; 5 F; $c^2 = 0.000$; df = 1; $P = 1.0000$), road cruising (0 M; 2 F; $c^2 = 0.500$; df = 1; $P = 0.4681$), or all capture methods combined (11 M; 11 F; $c^2 = 0.045$; df = 1; $P = 0.8793$). The juvenile:adult ratio of captured *P. cornutum* did not differ from the overall ratio of 1:1.6 for pitfall trapping (2 juveniles; 5 adults; $c^2 = 0.024$; df = 1; $P = 0.8941$), systematic searching (3 juveniles; 9 adults; $c^2 = 0.426$; df = 1; $P = 0.5204$), road cruising (1 juvenile; 1 adult; $c^2 = 0.188$; df = 1; $P = 0.7234$), or funnel trapping (4 juveniles; 1 adult; $c^2 = 2.173$; df = 1; $P = 0.1293$).

The two trapping methods and road cruising did not yield recaptured *P. cornutum*; however, systematic searches resulted in seven recaptured lizards. These recaptured lizards were initially caught by pitfall trap (N = 1), systematic search (N = 1), and random capture (N = 4). One lizard was recaptured twice during systematic searches.

Mortality of *P. cornutum* was not observed for pitfall and funnel trappings and systematic searches. Four *P. cornutum* were recovered dead from the dirt roads on the research area. Even though it was obvious these lizards were killed by vehicles, road cruising searches could not be determined as the cause of death. There was no mortality of *P. cornutum* during the time from capture to release for any method.

Search methods provided more captures per unit effort than trapping methods and road cruising provided more captures per

unit effort than systematic searches. Even though there was an order of magnitude difference in captures per unit effort between road cruising and funnel trapping, the monthly variation in capture rates caused there to be no significant differences in captures per unit effort when all capture methods were compared. Few studies report capturing horned lizards in pitfall traps and we found no studies where *P. cornutum* were captured in funnel traps. Rice et al. (1994) did not capture *P. cornutum* in pitfall or funnel traps in 19 days of trapping, but did capture *P. cornutum* in their study area by random searches. Parker (1971) captured 10 of 50 *P. solare* in pitfall traps over two years. Milstead (1959) collected 12 *P. modestum* with funnel traps in 18 days of trapping. Anecdotal information indicates horned lizards may have an aversion to pitfall traps. *P. cornutum* have been observed to approach drift fencing, turn 180° and move away from the fencing, rather than turn 90° and follow the fencing to the pitfall trap (M. Montemayor, pers. comm.).

The large number of recaptures in the systematic searches was surprising, while the lack of recaptures in the other three capture methods was not. In another Texas study conducted over several years, the researchers have captured in excess of 800 *P. cornutum* with a recapture rate of < 5% on initial recaptures and < 1% on subsequent recaptures (M. Montemayor, pers. com.). Six of the seven recaptures in this study occurred in the study plots which were grazed by livestock. These plots were free from tall herbaceous vegetation due to heavy grazing, thus making it easier to locate the lizards.

Each of the assessed capture methods has positive and negative aspects. Pitfall and funnel trapping require only one person to operate, do not require active monitoring, and can be permanent structures (funnel traps can be moved daily if needed). However, these methods are costly to set up in both time and money. Current prices (1996) for aluminum flashing (used as drift fences in the pitfall arrays) and hardware cloth (used in the construction of funnel traps) are US $15.50 per 7.6 m by 45 cm roll and approximately $2 per trap, respectively. Additionally, pitfall traps require frequent maintenance to keep paths around the drift fences clear of vegetation and debris, and to repair erosion around the buckets and flashing. Several instances occurred when funnel traps required mending because captured rodents chewed holes through the hardware cloth.

In contrast, road cruising and systematic searches required no setup time and were time efficient (a large area was covered in a short amount of time). Road cruising requires only one person to conduct; however, this method requires many secondary roads to yield sufficient numbers of lizards and these roads need to be maintained free of tall grass and ground litter to increase the probability of observing lizards. Also, road cruising is a potential source of mortality for *P. cornutum*. If an estimate of population size is required, then systematic searches should be conducted. Most population estimation methods require mark-recapture data (Krebs 1989), and the systematic search was the only method assessed which provided this type of information. This method can be costly if searchers are paid; therefore, volunteer searchers (e.g., Boy Scout troops, local conservation groups, etc.) are recommended. However, observer bias can be great if some searchers look for lizards more thoroughly than others. Also, if an estimate of relative density is required, it would be best to maintain the same searchers for each area to minimize observer bias.

The capture methods were analyzed in terms of captures per effort, but often effort is not the limiting factor in a study. Financial constraints are more commonly the limiting factor and this study did not include this component in the analysis. All four capture methods can be economically consuming. However, if *P. cornutum* are required in a short period of time, the following recommendations are offered. If secondary roads are abundant on the area of interest, then road cruising is recommended to yield the best capture rate per unit effort. If the area of interest has few secondary roads but searchers can be obtained, then systematic searches may prove to be the most productive method of capture. If secondary roads and number of searchers are limiting factors, then a trapping method is the best option; funnel traps are less expensive per unit. Researchers need to determine which factors are limiting, and then choose the capture method best suited for their available resources.

Acknowledgments.—We thank the many volunteers who helped in the systematic searches. The Wildlife Preservation Trust International, Inc., Houston Livestock Show and Rodeo, and Caesar Kleberg Wildlife Research Institute all graciously provided financial support. Texas Tech University provided materials for the project.

Basic data on vertebrate activity are difficult to obtain for many species in quantities sufficient for documenting patterns. To alleviate this problem, we designed a camera device to record the time, day, and identity of every vertebrate entering or exiting a gopher tortoise (*Gopherus polyphemus*) burrow. The apparatus may be modified for use with other vertebrates.

For a camera, we use a Canon™ Sure Shot Max/Date with a modified shutter release. Removing the plastic button (with hemostats) exposes four contacts; separate 30 gauge wires are soldered to three of these contacts at the points shown in Fig. 1. Each wire exits, and is cut 1" beyond, the hole left by the shutter release button, and remaining space is filled with hot glue to protect the soldered connection and immobilize the wire. Wires attached to points 1 and 2 (Fig. 1) are twisted together and soldered to an 18 gauge wire, the wire attached to point 3 is soldered to another 18 gauge wire, soldered connections are protected with shrink wrap, and the two wires are cut to a length of ca. 6". The carrying strap is removed from the camera and both wires are immobilized against the strap hole with a plastic bundle holder. Terminal ends of the wires are then attached to the female end of a two-pole quick connect; this latter arrangement reduces strain on the solder joint when the camera is connected to, or disconnected from, other components.

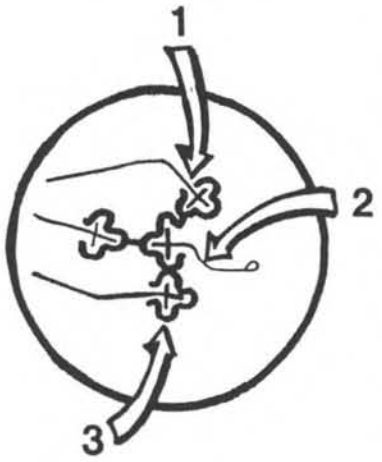

FIG. 1. Schematic of circuit board in camera used to trigger the shutter. Numbered arrows show points where 30 gauge wire is soldered to link camera shutter to timer box.

The base of the pressure switch (Fig. 2) consists of 10" diameter PVC pipe cut into 3" x 8" rectangles. A 1/8" hole, started on the convex side and countersunk through half the thickness of the PVC, is drilled at each end and a piece of masking tape is placed across the convex side of one end; this covers the terminal 1" of the base. The top (convex side) of the base is painted with EMI-RFI shield paint (available from specialty electronics shops). After drying, the masking tape is removed, conical metal inserts are placed in the countersunk holes, a 1/8" bolt is placed through each hole from the top, and one lead from a 4' length of 18 gauge, two-lead, stranded wire is attached to each bolt and bolted from below. A "sensitive area" is established by placing 1/8" wide strips of zip-a-line in the shape of a rectangle (excluding both bolts, and leaving a 1/4" wide border) on the upper surface of the base (Fig. 2A). Then four strips of 1/16" wide zip-a-line are placed within this rectangular area at ca. 1/8" intervals (Fig. 2A).

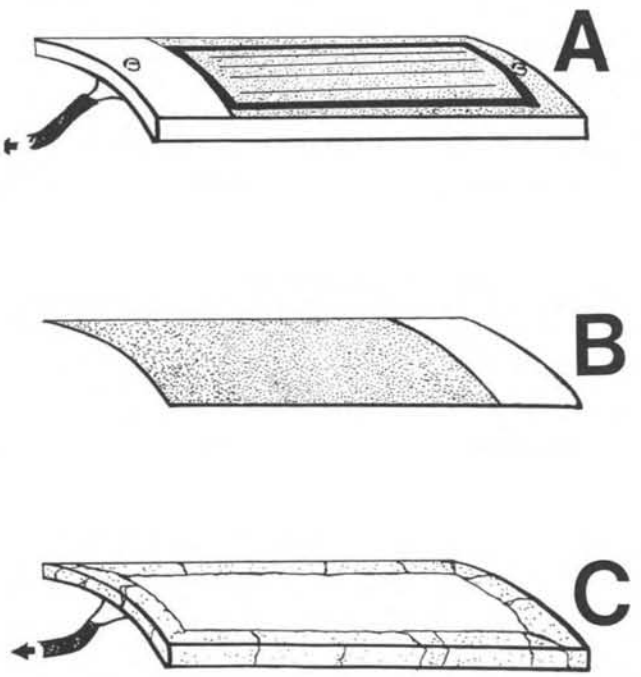

FIG. 2. Schematic of pressure switch. A) Base of switch (PVC); lead wires from timer box are bolted to the bottom at each end of the base. B) Top of switch (plastic transparency film) showing painted (bottom) side. C) Complete switch showing top attached to base with duct tape.

The top of the pressure switch, a 3" x 8" piece of clear plastic (we use 3M™ transparency film), is masked across one end and then spray painted with the EMI-RFI shield paint (Fig. 2B). A small bead of silicone sealant is then placed along the outer edge of the upper surface of the PVC (outside the "sensitive area"), and the top is added (painted side to zip-a-line side) so that its unpainted end overlaps the painted end of the base. The edge of the top is then secured to the PVC with duct tape (Fig. 2C). Within the pressure switch, the central painted portion of the plastic top avoids contact with the painted central portion of the PVC because of the zip-a-line. Any organism heavy enough to deflect the top so that the shield paint contacts the painted portion of the base completes a circuit that triggers the timer box.

Timer box circuitry (Fig. 3) is placed inside a protective metal box, the outside of which is shown (Fig. 4). Three wires enter the box, one from the pressure switch [hardwired; the lead wire from the switch must pass through a hole in the protective tub (see below)], one from the male end of a quick release (also hardwired; allows the camera to be detached from the timer box), and a third one to connect the timer circuitry to a 12 volt battery. The face of the timer box (Fig. 4) has three toggle switches, a test light, and a rheostat control. The toggles turn power on or off, send signals from the pressure switch to a test light or camera, and engage or disengage a variable delay set by the rheostat; if the rheostat is not engaged, a six second delay between successful triggerings of the pressure switch is effected. This minimum delay reflects the ability of the camera to recharge the flash and auto focus after each exposure. The rheostat, however, allows a variable delay

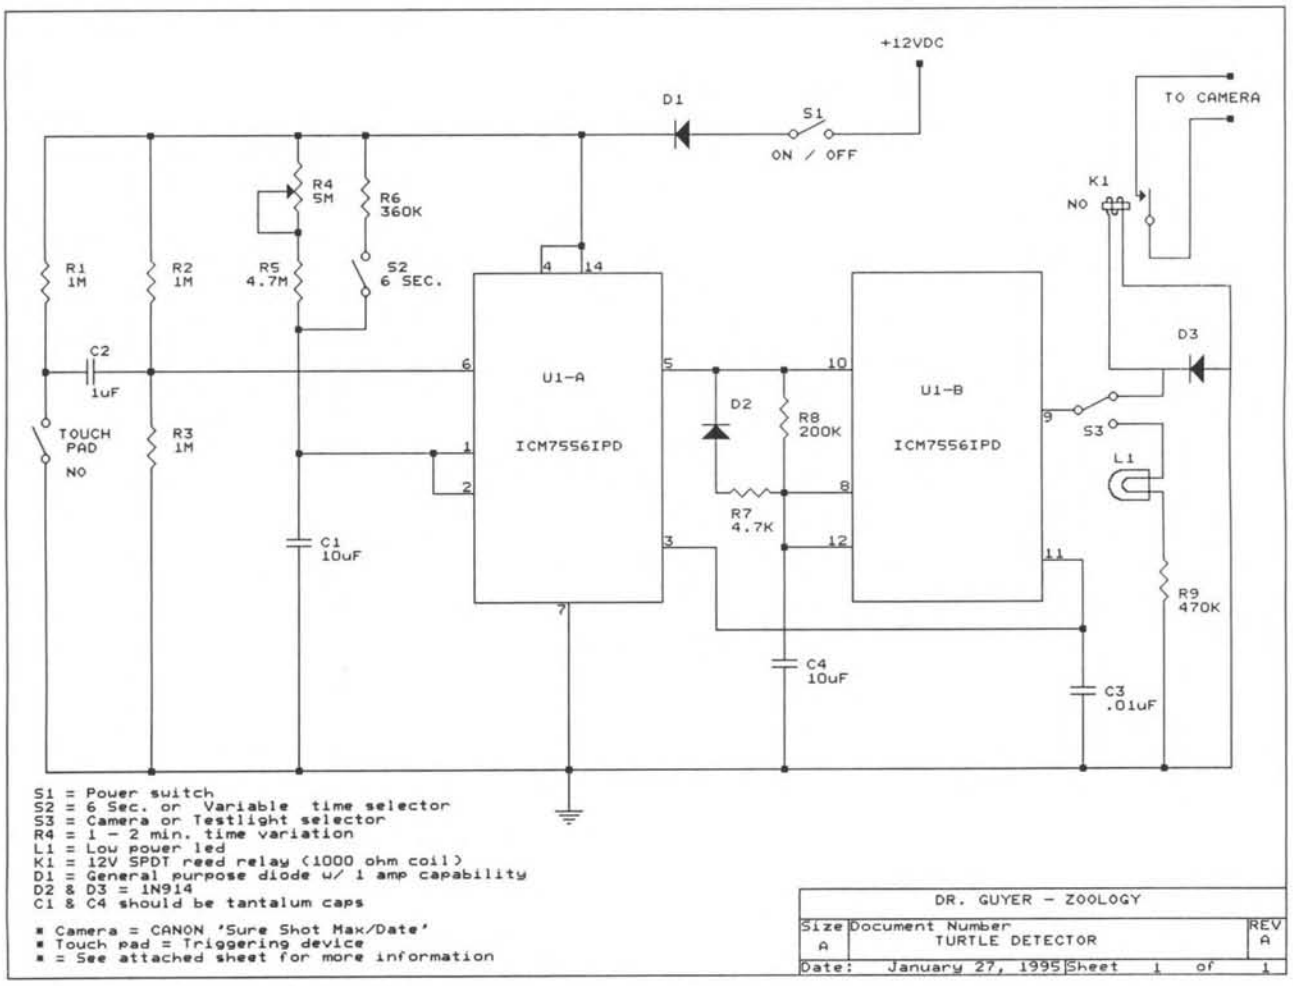

FIG. 3. Schematic of timer box circuitry. S1, S2, and S3 are switches (normally open) located on the front of the timer box (Fig. 4). R1, R2, R3, R5, R6, R7, R8, and R9 are resistors; R4 is a 1–2 min rheostat control. D1 is a general purpose diode with 1 amp capability and D2 and D3 are 1N914 diodes. C1, C2, C3, and C4 are capacitors (C1 and C4 are tantalum caps). K1 is a 12 V SPDT reed relay (1000 ohm coil). L1 is a low power LED. U1A and U1B are components to an integrated circuit timer.

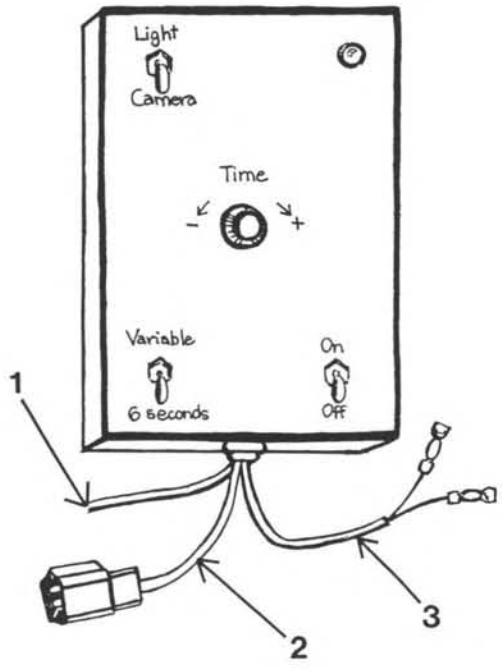

FIG. 4. Arrangement of control switches on timer box.

between camera shots; our current model can be adjusted between one and two minutes.

The timer box and pressure switch require a 12 volt, 1.2 amp·hr battery (we use Power Sonic™ model PS-1212); batteries last 1–2 weeks between rechargings. The camera's clock is run by a 3 volt lithium watch battery (CR 2025) that is expected to last ca. 3 years, and the flash and autofocus are run by a 3 volt lithium battery (CR 123 A/DL 123A) that is advertised to last through ca. 400 exposures (at 50% flash). For the latter, however, we find it necessary to check the charge every 1–2 weeks; batteries run down rapidly in the field.

To keep the camera free of dust and moisture, we use a plastic tub (Rubbermaid™ 3 quart, rectangular) with a tight fitting lid (Fig. 5A). On one side of the tub, we cut an opening following the outline of the camera (Fig. 5B) and cover this opening with plastic window material or plexiglass cut to size and fixed to the outside of the tub with silicone sealer. The side of the tub that now faces up becomes the top of the device in the field; a steel rod cut to ca. 2 ft. in length is now attached to the tub with two U-bolts that must pass through holes drilled through the top. Nuts are tightened on the bolts from inside the tub and the rod is positioned so that it passes beyond the tub for a distance of at least 1 ft. (Fig. 5A). We then attach a right-angle clamp to the rod so that it can be secured to a ring stand in the field. A 1/8" hole is drilled into the bottom of the tub, through which the wire from the pres-

sure switch passes (Fig. 5B) on its way to the timer box (Fig. 4).

Strips of styrofoam cut and glued to the inside of the tub hold the camera in place. The camera must be switched to auto flash, and the lens shutter opened, when placed in the field; to avoid draining the 3 volt battery, the camera lens shutter should be closed when the camera is not in use. The 12 volt battery is connected to the timer box and placed behind the camera (this also helps maintain the camera in position). The timer box then is switched to the desired settings and placed into the tub. Before the lid is placed on the tub, a small paper envelope with Drierite is added to control moisture.

The camera device is positioned by placing a ring stand behind a burrow entrance and clamping the protective tub to the stand. A single pressure switch is placed so that burrow occupants must cross it; switches can be linked with parallel circuitry so that the area covered is suitable for large burrows, or the size of the base can be modified.

Our camera device cost ca. US $175, which makes it comparable in price to a radio transmitter (assuming no labor costs). In field settings, the camera can document activity patterns, as can telemetry. We have used both technologies in studying gopher tortoises and feel that the camera method has the advantage of greater precision in that the length of time that an animal is in or out of a burrow can be measured. Comparable precision with telemetry gear requires relatively expensive data loggers and antennae. In addition, all animals entering a burrow, not just those with radios, can be assessed with the cameras. Additionally, if 10–15 cameras are available (the number of radios used in a typical telemetry project) they can be arranged at neighboring active burrows to determine the potential for social interaction. The primary disadvantage of the camera method is triggering of the pressure switch during rain storms. Associated with this is a greater cost in the film and film processing necessary to assess activity.

Acknowledgments.—This project was supported, in part, by The Nature Conservancy and the Alabama Agricultural Experiment Station.

HERPETOLOGICAL HUSBANDRY

Captive Breeding of *Eleutherodactylus antillensis* (Anura: Leptodactylidae) from Puerto Rico with Notes on Behavior in Captivity

SCOTT F. MICHAEL
Department of Microbiology, 620 LHRB
University of Alabama at Birmingham, Birmingham, Alabama 35294, USA
e-mail: scottm@uab.edu

Frogs of the genus *Eleutherodactylus* form a species-diverse and ecologically dominant element in many neotropical anuran communities. Due to its enormous size, this genus provides an excellent opportunity for investigations into the mechanisms of adaptive radiation and sympatric evolution. However, little is known of the life-histories of the majority of the 500-plus described species. Life history studies have been hindered by the fact that the majority of *Eleutherodactylus* species are nocturnal, cryptically colored, and wary. In addition, most are territorial breeders, with individuals often widely distributed throughout their habitat. As a tool for study of the basic ecology of these frogs, methods have been developed to breed certain species in captivity (Michael 1995). Here, observations of the captive reproductive behavior of another species, *Eleutherodactylus antillensis*, are reported.

Eleutherodactylus antillensis is a small to medium sized species (adult SVL 30–36 mm) occurring nearly island-wide in Puerto Rico (except for high elevations) and on several of the Virgin Islands (Rivero 1978; Schwartz and Henderson 1991). One female (49 mm SVL) and five male (33–36 mm SVL) frogs were collected from shrubs and low plants from roadsides and other open areas along Route 186, near El Verde field station (350 m elevation) in the Luquillo Mountains of Puerto Rico. These specimens are somewhat larger than the sizes previously reported for this species, and may reflect a difference in size in populations from different sites.

In captivity, frogs were housed in 10-gallon, glass aquaria (51 cm [length] x 26 cm [width] x 32 cm [height]) with regulated moisture, heat (25–27°C during the day, 21–23°C during the night), and light (12 h photoperiod), as previously described (Michael 1995). Retreat sites were provided by the inclusion of potted bromeliads (*Guzmania* and *Vriesea* sp.) and 1–4 cm deep piles of moist peat moss on a substrate of pebbles. Whenever possible frogs were fed a variety of moths attracted to outdoor lights, various spiders, grasshoppers, termites, and other insects captured locally in Alabama. During the winters, the diet consisted almost entirely of crickets (*Acheta domesticus*), house flies (*Musca domestica*), and fruit flies (*Drosophila melanogaster*).

For investigation of breeding behavior, a single male was generally housed with the female. The other males were housed together in other tanks. In captivity, males produced typical vocalizations, consisting of both the rapidly repeated two-note advertisement call as well as a call consisting of a series of short clicks (Drewry and Rand 1983). This second call has been shown recently to have an aggressive function (Ovaska and Caldbeck 1997a). Typically, the male housed with the female was more vocal than other males. The female was not heard to vocalize on any occasion. This is in contrast to females of the closely related species *E. coqui* and *E. cochranae* which both utilize aggressive vocalizations (Michael 1997; Stewart and Rand 1991, 1992).

Each of three males was used separately for breeding. Inclusion of more than one male with the female resulted in mating interference behaviors which precluded successful breeding. Separately, each courted and successfully mated with the female. Courtship usually took place during the early evening, similar to *E. coqui* and *E. cochranae* (Michael 1995; Townsend and Stewart 1986, 1994). The males generally began courtship by producing advertisement calls interspersed with territorial calls, then changed to the softer courtship call upon the approach of the receptive female (Michael 1996). A similar courtship has been described recently for *E. antillensis* from the Virgin Islands in the wild (Ovaska and Caldbeck 1997b). During a successful courtship, the male would lead the female down an excavated tunnel within the soil of one of the potted bromeliads. All of the egg clutches were deposited in these tunnels.

When two or more males were housed together with the female, mating was always unsuccessful. One male would assume a dominant role and call to the female and the other would assume a satellite role and remain quiet, near the calling male. Upon initiation of courtship, all three frogs would attempt to enter the nest site. Since the nest sites were all in excavated burrows, it was difficult to determine subsequent events. On two occasions the nest sites were exposed during courtship by removing the bromeliad from the pot. On both occasions all three frogs were found together in amplexus. Amplexus in these situations, as well as with only one male, seemed to consist of the males loosely laying on top and somewhat to the rear of the female. There was no evidence of clasping; however this may have been missed because of the difficulty in observing the frogs and disturbance to the frogs during observation. No eggs were found during examination of the nest site after three courtships where more than one male was present, even though the female showed evidence of having laid eggs (as determined by thinness and lack of white abdominal egg masses). The eggs were most likely eaten by one or more of the frogs, although eggs could not be clearly seen in the abdomens of any of the frogs.

The three males used for breeding each fathered multiple clutches (male A: 7; male B: 4; male C: 8). The matings with any one particular male were consecutive and breeding continued yearround. Every male placed with the female successfully mated. The number of eggs per clutch ranged from 11 to 32 (mean = 24; SD = 8; N = 9). Egg size was 4–5 mm at deposition, but the jelly coating swelled to a total diameter of 6–7 mm within a few days. The interval between clutches was extremely variable and depended on both the readiness of the male, as well as the feeding schedule of the female. The minimum breeding interval was eight days.

As a test for the utilization of internal fertilization in this species, male removal experiments were carried out during five of the oviposition events mentioned above (once with males A and B and three times with male C). During these experiments the courtship was monitored carefully and the male was removed from amplexus after a period of time had passed. Experiments were performed such that the male was removed 1.25 h, 5 h, 5.5 h, 6.5 h, and 7.66 h after the pair initially entered the nest site. After male removal, which usually resulted in both frogs abandoning the nest site, the female returned to the nest site within an hour and deposited eggs; apparently, once ovulation is initiated at the beginning of courtship the female is obligated to deposit eggs. During the 7.66 h trial the female had already deposited some of her eggs before the male was removed. The eggs from these experiments were monitored for several days for development. None developed except for the eggs that already had been laid during the 7.66 h time point, all of which developed normally. These

experiments indicate that *E. antillensis* apparently does not utilize internal fertilization as has been reported for *E. coqui* (Townsend et al. 1981) and the ovoviviparous species *E. jasperi* (Wake 1978).

To determine the extent of parental care in this species the fathers were monitored closely for several days following undisturbed mating. They tended to use excavated tunnels in the bromeliad pots as diurnal retreats, sometimes in the same pot as the clutch of eggs. However, in no case were the fathers ever found sitting directly on top of the eggs. In only one case was a father found in contact with the eggs, and then only with the very edge of his hind foot. This is in contrast to other Puerto Rican species— *E. cochranae, E. cooki, E. coqui*, and *E. hedricki*—in which male frogs have been documented to sit on and actively guard their clutches (Grant 1932; Michael 1995; Rivero 1963; Townsend et al. 1984). The female was also never found attending the eggs, as has been documented for several non-Puerto Rican species (reviewed by Townsend 1996), but tended to utilize a particular bromeliad axil as a diurnal retreat, regardless of the oviposition site.

A previous report, based on observation of a small introduced population of *E. antillensis* in Panama City, Panama, mentions that eggs are cared for either in turns or together by both parents (De Sousa et al 1989). However, an earlier and more detailed publication by the same authors indicates that only females were ever observed with the eggs, and then in only a small percentage of cases and never with eggs that were more than six days old (Castillo and Mayorga 1984). These observations are interesting as female egg attendance has never been reported for any other Puerto Rican species. Differences between these previous observations and those presented here may be due to behavioral differences between populations from Puerto Rico and Panama. Female parental care may also have been missed in this report due to the study of only a single female. In any case, it is clear that *E. antillensis* does not exhibit the same level of parental care as other Puerto Rican species. It is possible, however, that *E. antillensis* parents provide a considerable amount of protection to their eggs simply by defending an area of surrounding territory without actually maintaining contact with the clutch.

Hatching times for clutches for which exact deposition and hatching dates were known ranged from 12–20 days (mean = 18; SD = 2; N = 5). Hatchling size was 4–6 mm SVL (mean = 5; SD = 1; N = 8). Hatchlings were maintained in small, clear acrylic boxes (12 x 12 x 10 cm tall) with a crumpled, moistened, unbleached paper towel inside. These small cages then were placed inside an appropriately heated and lit aquarium. The tiny froglets were too small to eat fruit flies and were initially fed a diet of small springtails (*Folsomia candida*). Newly hatched *E. antillensis* were apparently completely developed and began to hunt actively and eat within several hours of hatching. This is in contrast to hatchling *E. coqui* and *E. cochranae* which generally remain in the nest site under parental protection for three to five days before dispersing to find food. Even when removed from the father, hatchlings of these two species do not eat for several days. The ability of *E. antillensis* hatchlings to hunt and consume prey immediately lends support to the observed lack of parental care.

Feeding springtails to the hatchling frogs allowed 90–100% to grow to a size where they were able to eat fruit flies, as opposed to the 95% mortality reported previously for *E. coqui* and *E. cochranae* that were not fed springtails (Michael 1995). However, a diet of springtails and fruit flies alone resulted in developmental problems similar to those reported previously for *E. cochranae* (Michael 1995). Subsequent hatchlings were fed a diet heavily supplemented with small insects locally collected in Alabama. These small insects were collected with a sweep net and potentially dangerous spiders, bees, large ants, and other noxious insects were removed. On this diet, juvenile frogs developed well. The three fastest developing frogs reached maturity and began to call (indicating that they were male) in five months, at which point they measured 22–25 mm SVL.

Captive breeding of *E. antillensis* has allowed the intimate observation of biologically interesting behaviors that are difficult to observe in the field. These include territorial and mating behaviors which indicate differences in the biology of *E. antillensis* compared to other *Eleutherodactylus* species.

Acknowledgments.—I thank Emigdio and Mariyu Isern for their hospitality, Sharon Isern and Richard Elinson for field assistance, Kristiina Ovaska for sharing unpublished data, Jack Cover for the springtail culture, and P. Rios and J. A. Gonzalez Liboy for issuing collecting permits.

Lakewood, Colorado 80226, USA

The boreal toad, *Bufo boreas*, historically occupied habitats primarily between 2590 m and 3350 m elevation in Colorado (Hammerson 1986). Interest in this toad has increased with the realization that populations in the southern Rocky Mountains have undergone significant declines in the past several years (Carey 1993; Corn et al. 1989). In November 1993, this toad was added to Colorado's list of Endangered Species (Buhlmann 1994). In addition, it is a candidate species for listing as Endangered by the U.S. Fish and Wildlife Service with the current federal status of "warranted but precluded" (U.S. Fish and Wildlife Service 1995). Here we compare the historical elevational range occupied by this species in the Colorado Front Range with its current elevational range.

We determined the historical elevational range for *Bufo boreas* in the Front Range based on 35 records in Boulder and Gilpin counties made before 1988. Localities were obtained from a database (Colorado Division of Wildlife, 1994) and records from Campbell (1970), Oder (1932), Ellis and Henderson (1913), Johnson (1932), Cynthia Carey (pers. comm.), and personal observations. Most of the records in the database are based on museum records. Campbell (1970) and Oder (1932) provided information on sites where breeding by this species was observed.

Current elevational distribution was determined from 22 observations made during 1993 and 1994 in Boulder, Clear Creek, and Gilpin counties during surveys conducted by the U.S. Forest Service and Colorado Division of Wildlife. These observations include data from extensive 1994 survey work and from less systematic surveys made in 1993. Most survey effort (ca. 94%) was made at elevations between 2500 and 3400 m. Three of the sites with toads observed in 1994 were among the 20 historical sites we were able to survey.

Historical *Bufo boreas* sites in Boulder and Gilpin counties ranged in elevation from ca. 2450 m at Boulder (= Barker) Dam, (Colorado Division of Wildlife 1994) to ca. 3480 m at King Lake (Campbell 1970).

The sites at which toads were observed in Boulder, Clear Creek, and Gilpin counties in 1993 and 1994 ranged between 2390 m and 3640 m (N = 22) (Fig. 1). Elevation ranged from 2630–3350 m at seven historical breeding sites and 2840–3280 m at nine observed breeding sites (Fig. 2).

Campbell (1976) reported a high elevation record of 3615 m for this species in the San Juan Mountains of southern Colorado. The observation of a female *Bufo boreas* on 27 August 1993 at an elevation of 3640 m in the Woods Creek drainage (Clear Creek County, Colorado) represents a new high elevation record for this species. This species ranges above this elevation, however, as Campbell (1976) noted that one individual must have moved across a 3661 m pass, as it was observed on both sides.

Our observation of a toad at 2390 m is at a lower elevation than the historical record in the Front Range (2450 m). The lowest elevational records from both historical and observed sites along the Front Range are well above the low elevation records from elsewhere in Colorado. The lowest elevation records from Colorado include Pagosa Springs (2164 m) and "3 miles E, 4 miles S Collbran" (ca. 2070 m). However, the collection data for some of these records may be inaccurate (Hammerson 1986).

Survey work in southern and eastern Wyoming indicates that the elevational range there may be contracting, with this species disappearing at higher elevations. For example, in the Medicine Bow Mountains of southeastern Wyoming, historical records previously ranged up to 3200 m elevation. Data from recent surveys indicate that toads are now absent from elevations above 2925 m (Christopher Garber [deceased], Wyoming Nature Conservancy, pers. comm.).

Caution needs to be exercised in comparisons made between historical and observed elevational distributions of boreal toads. First, older records often lack precision, making it difficult to determine the precise site (and therefore the elevation) of the observation. Also, there can be considerable bias in data collection, particularly for a species as common as this toad once was. For example, Campbell (1970) reported several high-elevation occur-

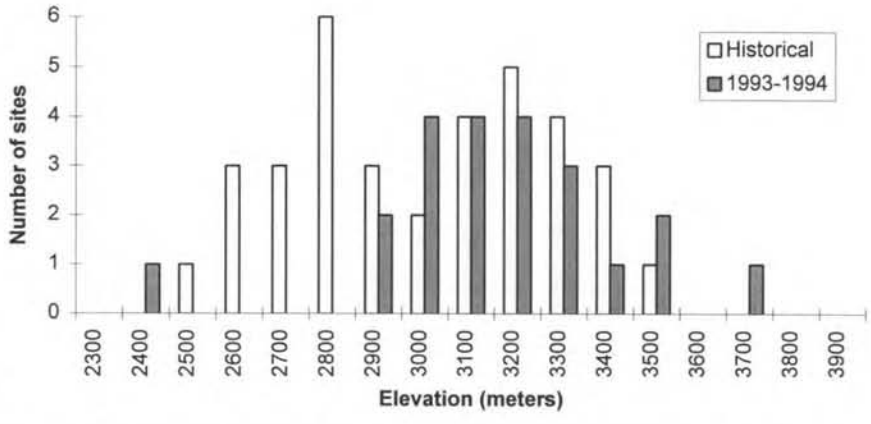

FIG. 1. Boreal toad historical and observed (1993–1994) elevational distribution.

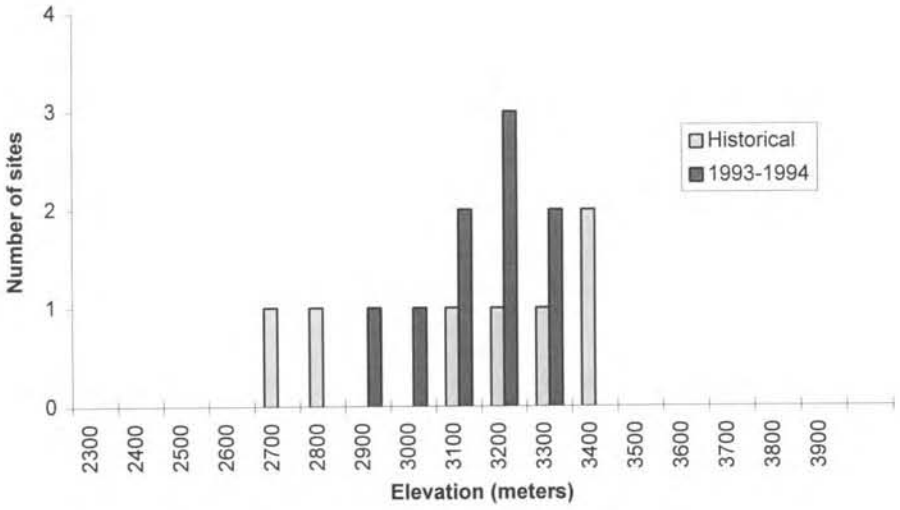

FIG. 2. Elevational distribution of historical and observed (1993–1994) boreal toad breeding sites.

rences that were not represented elsewhere. Museum and literature records seldom mention whether breeding was observed at the site where a specimen was taken (Corn et al. 1989). Explicit mention of breeding or of tadpoles was made for only seven of the historical sites—almost certainly sexual activity must have been occurring at a much greater proportion of the recorded localities. Finally, our survey work was not evenly distributed across the elevational range occupied by this species, but instead was biased for sites above 2500 m elevation.

When a species that occupies a broad elevational range undergoes population declines, it is probable that the elevational range occupied will contract as well. This effect can be noted in areas with only a few remaining populations (such as in the Medicine Bow Mountains of southeastern Wyoming).

Bufo boreas populations in the Southern Rocky Mountains have declined from historical levels, including in our survey area. In the Colorado Front Range this toad still appears to occupy much the same elevational range as it did when it was more common. In fact, our data include a new high elevation record and a low elevation record that matches historical low elevation occurrence. However, there may be some elevational range contraction in current breeding sites when compared with historical breeding sites.

Acknowledgments.—Great Outdoors Colorado funded 1994 survey work, and was administered by Rebecca Parmenter (U.S. Forest Service) and Tom Nesler (Colorado Division of Wildlife). Most of the 1994 field work was performed by Tamara Holmes, David Barrett, and Adam Walters. P. Stephen Corn commented on an early draft of this note.

ANURA

BUFO VARIEGATUS (Eden Harbour Toad): ARGENTINA: SANTA CRUZ: shores of Lago del Desierto and Río de las Vueltas, 49°05'S, 72°54'W, 420 m elev. 10–12 December 1996. Néstor G. Basso, Carlos A. Galliari, Gustavo R. Spinelli, and Jorge D. Williams. Verified by Gustavo Carrizo. MLP A 1281–84. Reproductive adults, juveniles and tadpoles were found in a shallow eutrophic limnotope fed by groundwater ("mallín"), surrounded by the temperate forest of lenga (*Nothofagus pumilio*). Adults and juveniles also were found at night crossing the road bordering the Río de las Vueltas, near Lago del Desierto. Tadpoles were observed forming aggregations of several individuals. *Bufo variegatus* is distributed in Chile in the Andean range of the *Nothofagus* forests, from Malleco (ca. 39°S) to the Magellanic channels (ca. 52°S) (Cei 1962, Batracios de Chile. Univ. Chile, Santiago. cviii+128 pp; Formas 1978, J. Herpetol. 12:243–246). The southernmost population of *B. variegatus* in Argentina was recorded from the western shores of Lago Belgrano, Perito Moreno National Park, Santa Cruz province, 47°48'S, 72°22'W, 950 m elev. (Biolé and Williams 1984, Neotropica 30(84):243–244). This discovery extends the distribution of the species 150 km southwards in the Argentinian Patagonian forest.

Submitted by **NESTOR G. BASSO**, Instituto de Limnología "Dr. Raúl A. Ringuelet," Casilla de correo 712, 1900 La Plata, Argentina, and **JORGE D. WILLIAMS**, Departamento Zoología Vertebrados, Museo de La Plata, Paseo del Bosque s/n, 1900 La Plata, Argentina.

BUFO WOODHOUSII FOWLERI (Fowler's Toad). USA: ALABAMA: WINSTON CO: William B. Bankhead National Forest, ca. 1.5 km NE Adkins Cemetery. N 1/2 Sec. 16, T9S, R8W. 5 October 1996. AUM 34300. This record was obtained during ongoing amphibian surveys conducted by the Pike/San Isabel National Forest and Colorado Division of Wildlife.

Submitted by **CRAIG FETKAVICH**, U. S. Forest Service, Pike/San Isabel National Forest, 1920 Valley Drive, Pueblo, Colorado 81008, USA; **LAUREN J. LIVO** and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

RANA CLAMITANS CLAMITANS (Bronze Frog). USA: TEXAS: FORT BEND CO: Brazos Bend State Park; 26.1 air km ESE Rosenberg. 8 March 1997. John H. Malone. Verified by James R. Dixon. TCWC 75129–30. County record; fills gap between Austin, Brazoria, and Harris counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). A juvenile specimen (TCWC 75129; 34 mm SVL) was collected at Site 30; located SW of Creekwood Lake; 27 m W on Big Creek washout trail. An adult female specimen (TCWC 75130; 78 mm SVL) was collected at Pilant Lake. Both animals were found during an amphibian breeding site survey conducted for the Texas Department of Parks and Wildlife in order to construct a long term amphibian monitoring program at Brazos Bend State Park. Numerous (>25) other individuals of this frog, both adult and juvenile, were observed from various sites at the park.

Submitted by **JOHN H. MALONE**, Department of Wildlife and Fisheries Science, Texas A&M University, College Station, Texas 77843, USA.

SCINAX SQUALIROSTRIS (Striped Snouted Treefrog). BRAZIL: DISTRITO FEDERAL: BRASÍLIA: ÁREA DE PROTEÇÃO AMBIENTAL DO CAFURINGA: Fazenda Santa Elisa (ca. 15°35'S, 48°02'W). 1 February 1995. R. A. Brandão, B. A. Duar, M. G. Zatz and M. A. Bagno. Museu Nacional (MNRJ 17420). Verified by J. P. Pombal, Jr. Original distribution was southwestern Brazil, southern Paraguay and Uruguay, and northeastern Argentina (Frost 1995, Amphibian Species of the World. Version 2/95. Eletronic manuscript, Herpetologists' League). First record for central Brazil; extends distribution to the north.

Submitted by **REUBER A. BRANDÃO, BRUNO A. DUAR,** and **ANTONIO SEBBEN,** Laboratório de Fisiologia Animal - CFS-IB, Universidad de Brasília, 70.910-900, Brasília-DF, Brazil.

SPEA BOMBIFRONS (Plains Spadefoot). USA: TEXAS: HALL CO: Caprock Canyons State Park, Caprock Canyon Trailway, 1 mi S and 9 mi W Estelline. 18 July 1996. F. D. Yancey, II. The Museum of Texas Tech University (TTU 11629). Verified by Clyde Jones. New county record; fills gap between Donley and Motley

counties, and helps define eastern margin of range in Texas Panhandle (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II**, Department of Biological Sciences and The Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

SPEA INTERMONTANA (Great Basin Spadefoot). USA: IDAHO: NEZ PERCE CO: Salmon River, UTM Zone 11, 521918E, 5092777N (m)(NAD 27). 17 June 1995. Robin L. Llewellyn. Idaho Museum of Natural History (IMNH 1481). Verified by Charles R. Peterson. One adult was found dead along the Salmon River Road on Craig Mountain. New county record (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow. 332 pp.).

Submitted by **ROBIN L. LLEWELLYN**, Department of Biological Sciences, Idaho State University, Campus Box 8007, Pocatello, Idaho 83209, USA.

SYRROPHUS CYSTIGNATHOIDES (Rio Grande Chirping Frog). USA: TEXAS: NUECES CO: 28°19'05"N, 98°33'40"W, within Corpus Christi city limits, Waldron Naval Air Landing Field. 1 September 1995. Travis W. Taggart and Richard Anderson. TCWC 75128 (alcoholic); Southeastern Louisiana University Tissue Collection (SLU cat. no. pending, frozen tissues). Verified by Brian I. Crother. Three adults found by day under discarded plywood at a dump. Fourteen adults collected at night while chorusing from laurel oaks, cattails, and from the tops of 1 m tall grass clumps. Represents third disjunct Texas population associated with a large city (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). The other Texas populations established outside of the Rio Grande valley are in Bexar (San Antonio) and Harris (Houston) counties.

Submitted by **TRAVIS W. TAGGART**, Department of Biological Sciences-SLU 736, Southeastern Louisiana University, Hammond, Louisiana 70402, USA.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: GEORGIA: WHITE CO: Chattahoochee National Forest, Georgia Rt. 255 Spur (301), 0.16 km S Sautee Trail/Georgia Rt. 255 Spur (301) jct. (entrance to Skylake private residential community). 27 October 1996. Michael G. Frick and Anne M. Lindsay. Savannah Science Museum (SSM 96.13763). Verified by John B. Jensen. New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Publ. 3:1–712). Specimen was caught crossing road at ca. 1530 h.

Submitted by **MICHAEL G. FRICK** and **ANNE M. LINDSAY**, Savannah Science Museum, 4405 Paulsen Street, Savannah, Georgia 31405, USA.

GRAPTEMYS GEOGRAPHICA (Common Map Turtle). USA: WISCONSIN: KENOSHA CO: Powers Lake on NE shore, NE part of Sec. 18, T1N, R19E. 18 August 1994. M. G. Bolek. Milwaukee Public Museum (MPM 29588). Verified by G. S. Casper. New county record Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus. 87 pp.). Six turtles were observed on the Kenosha County side of the lake and the specimen was captured for identification and voucher.

Submitted by **MATTHEW G. BOLEK**, Department of Biological Sciences, University of Wisconsin Milwaukee, Milwaukee, Wisconsin 53201, USA.

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow Mud Turtle). USA: MISSOURI: CLAY CO: Kansas City North, near jct of 50th and Bristol Streets. 19 September 1993. Keith Gammon. KU Color Slide 11248. Verified by Joseph T. Collins. Specimen is alive at Lakeside Nature Center, Kansas City, Missouri, and will be deposited in the Bobby Witcher Memorial Collection at Avila College, Kansas City, Missouri, upon its death. Specimen is a female with a carapace length of 108 mm. County record; represents another locality as described by Smith and Blake from adjacent Ray Co. (1990, Herpetol. Rev. 21:40) near the Missouri River, and probably is due to an individual turtle being carried by flood waters. In fact, this record is temporally associated with the extreme flood conditions present in the Midwest during the summer of 1993.

Submitted by **KEVIN D. HOGAN**, Lakeside Nature Center, 5600 East Gregory Boulevard, Kansas City, Missouri 64132, USA, and **DONALD D. SMITH**, Division of Allergy and Rheumatology, University of Kansas Medical Center, 3901 Rainbow Boulevard, Kansas City, Kansas 66160, USA.

PSEUDEMYS CONCINNA SUWANNIENSIS (Suwannee River Cooter). USA: FLORIDA: TAYLOR CO: Econfina River, from U.S. Rt. 98 to ca. 2 km N of Gulf of Mexico. 29 October 1996. Dale R. Jackson. UF 105386 (specimen and 3 color slides). Verified by Paul Moler. On 21 April 1996, I observed from canoe ca. 2 dozen basking individuals, mostly immature animals between 90 and 200 cm estimated carapace length; a subadult female (plastron length 234 mm, CL 274 mm) was collected by basking trap on 29 October in the strongly tidally influenced lower river 4 km above the Gulf (NW 1/4 SW 1/4 Sec. 11, T5S, R4E). Probable presence in the river was first reported to me by M. A. Ewert based on 1960s sight records at U.S. Rt. 98. New drainage record (Jackson 1992, in P. Moler (ed.), Rare and Endangered Biota of Florida. Vol. 3. Amphibians and Reptiles, pp. 166–170. Univ. Press Florida, Gainesville; 1995, Chelonian Cons. Biol. 1:329–333) and first confirmed occurrence in any of the "small rivers" between the Aucilla and Suwannee. As such, this further reduces the conjectured disjunction between peninsular and panhandle populations of this species, which had been used by some to hypothesize separate specific identities for those populations (reviewed by Jackson 1995, *op. cit.*).

Submitted by **DALE R. JACKSON**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

STERNOTHERUS MINOR MINOR (Loggerhead Musk Turtle). USA: FLORIDA: TAYLOR CO: Econfina River, County Road 14A bridge at Shady Grove (NE 1/4, NE 1/4, Sec. 29, T2S, R7E). 27 October 1996. Dale R. Jackson. UF 105384–385 (9 specimens and color slides). Verified by Paul Moler. An adult male (carapace length 92 mm, plastron length 67 mm) and adult female (CL 90 mm, PL 71 mm) were collected in a sardine-baited hoop trap set on 26 October in the upper reaches of this small Gulf-draining blackwater river. Both specimens were much darker than conspecific turtles from Florida spring runs. Previously, on 21 April 1996, I observed a large adult basking on a branch ca. 6 km downstream of U.S. Rt. 98, ca. 34 straight-line km SW of the collection site and near the tidally influenced lower segment of the river; Fenholloway River at U.S. Rt. 27 (NE 1/4, NE 1/4, Sec 36, T4S, R8E). 7 October 1983. George M. Burgess et al. UF 104420. Immature (CL 63 mm, PL 44 mm). Verified by David Auth. These specimens not only represent new drainage records, but constitute the species' first confirmed occurrence in any of the small rivers between the Aucilla and Suwannee in Florida's "Big Bend" re-

gion; they thus help to close the geographic gap that previously appeared to separate panhandle from peninsular populations (Iverson 1977, Copeia 1977:502–517; Iverson and Etchberger 1989, Florida Sci. 52:119–144; Iverson 1992, A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana. 363 pp.).

Submitted by **DALE R. JACKSON**, Florida Natural Area Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: TEXAS: Floyd Co: UTM coordinates 14 307241E 3797536N. 18 July 1996. F. D. Yancey, II. The Museum of Texas Tech University (TTU 11632). Verified by Clyde Jones. New county record; fills gap between Hale and Motley counties (Dixon, 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II**, Department of Biological Sciences and The Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-Eared Slider) USA: OHIO: Mahoning Co: Lily Pond, Mill Creek Park. 23 February 1995. Raymond J. Novotny. Cleveland Museum of Natural History 6761. Verified by Timothy O. Matson. First county record. Conant [1951, Reptiles of Ohio. 2nd ed. (with revisionary addenda) Amer. Midl. Nat., Univ. Notre Dame, Indiana. 284 pp.]. This species has been observed at this site for at least 25 years (H. L. Vickers, 15 April 1970, "A Nature Diary," The Youngstown Vindicator). Female was observed laying eggs in lawn at Lily Pond during summer 1988; eggs were removed and hatched summer 1988, and most hatchlings were released at site. Female lived in captivity at nature center until death on above date. This species has been found at many localities outside of its range, Conant and Collins (1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co. Boston, Massachusetts. 450 pp.) Because of this breeding evidence in the Lily Pond and possibly at other lakes in Mill Creek Park, this should be considered an established colony.

Submitted by **RAYMOND J. NOVOTNY**, Ford Nature Center, Mill Creek Metropolitan Park District, 840 Old Furnace Road, Youngstown, Ohio 44511, USA.

SAURIA

ANOLIS CAROLINENSIS (Green Anole). USA: ALABAMA: Winston Co: William B. Bankhead National Forest, ca 1.5 km NE Adkins Cemetery. N 1/2 Sec. 16, T9S, R8W. 5 October 1996. AUM 34302. Verified by Craig Guyer. New county record (Mount 1975, The Reptiles and Amphibians of Alabama. Publ. Alabama Agric. Exp. Sta., Auburn. 347 pp.).

Submitted by **BRIAN P. BUTTERFIELD, DANIEL R. FRENCH, SCOTT R. FEARS, MICHELLE D. HARGREAVES, ANGELA J. LEWIS, CHRISTINE D. ROBY, LEAH M. HOOD,** and **JENNIFER R. ROBINSON**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

ANOLIS TRACHYDERMA (Roughskin Anole). PERU: Cusco: Canisea River, 250 m elev., 11°49'S, 72°47'W. 14 August 1996. Museo de Historia Natural Universidad Nacional Mayor de San Marcos, Lima (MUSM 16713, male; MUSM 16714, female). The male dewlap is larger than the female dewlap, and is orange with yellow on the anterior and posterior borders. The dewlap of the female is orange. This coloration is similar to that described for the species by Vanzolini [1972, Papéis Avulsos Zool. S. Paulo 26(8):95]. Both specimens were found sleeping on leaves 0.70–1.05 m above the ground. The previous northernmost locality in Peru for this anole was in the Utoquinia Region, Department Ucayali, on the border between Peru and Brazil (Avila-Pires 1995, Zool. Verh. Leiden 299:111).

Submitted by **VICTOR R. MORALES**, Department of Wildlife and Fisheries Sciences, and Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843-2258, USA.

COLOBODACTYLUS DALCYANUS (NCN). BRAZIL: SÃO PAULO: Parque Estadual Campos do Jordão, in montane forest in the Serra de Mantiqueira Range (22°45'S,45°33'W), ca. 1500 m. 14 February 1996. Ivan Sazima, Otavio C. Oliveira, and Marlies Sazima. Universidade Estadual de Campinas (ZUEC 01919). Verified by Marcio Martins. One unsexed specimen, 48 mm SVL, tail broken, 1.5 g body mass. First record from the state of São Paulo. Caught along roadside at 0930 h under a small rock. Extends the range of this species westward from previously known distribution (type locality in the Brejo da Lapa) on the NW flank of the Itatiaia massif on the border of the states of Rio de Janeiro and Minas Gerais [Vanzolini and Ramos 1977, Papéis Avulsos Zool., São Paulo 31(3):19–47].

Submitted by **PAULO ROBERTO MANZANI** and **IVAN SAZIMA**, Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, Campinas 13083-970, São Paulo, Brazil.

COPHOSAURUS TEXANUS TEXANUS (Texas Earless Lizard). USA: TEXAS: Floyd Co: Caprock Canyons State Park, Caprock Canyon Trailway, UTM coordinates 14 304470E 3790854N. 18 July 1996. F. D. Yancey, II. The Museum of Texas Tech University (TTU 11631). Verified by Clyde Jones. New county record; fills the gap between Briscoe and Crosby counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II**, Department of Biological Sciences and The Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

GEHYRA MUTILATA (Stump-Toed Gecko). FRENCH GUYANA: town of Kourou. J. C. Massary and I. Ineich. March-April 1996. Muséum National d'Histoire Naturelle, Paris (MNHN 1996.4342-4355 and 1996.4371). Verified by G. Pasteur. First report for South America; previously known from Indian and Pacific Oceans (Indoaustralian Archipelago). Extralimital from India and Sri Lanka through Indochina to Japan, the Philippines, and Indonesia. The species is often commensal with humans and has recently expanded its range throughout much of the world. It was introduced and established in México and San Diego, USA, and also into New Zealand where it did not become established (see Bauer and Henle 1994, Das Tierreich: Teilbd. 109:88–94). Occurs in sympatry with *Hemidactylus mabouia* in scattered localities in the town of Kourou where populations have been established for several years. The species will certainly spread rapidly to other towns on the heavily inhabited littoral part of French Guyana.

Submitted by **IVAN INEICH** and **JEAN-CHRISTOPHE DE MASSARY**, Muséum National d'Histoire Naturelle, Laboratoire de Zoologie (Reptiles & Amphibiens), 25 Rue Cuvier, F-75005 Paris, France.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: LOUISIANA: CALCASIEU PARISH: Lake Charles, McNeese State University campus. June 1968. James D. Lane. Seale Museum of Louisiana, McNeese State University (SML 1454); McNeese State University campus. 22 September 1996. Nick Slay. SML 9304–09; The city of Lake Charles. Spring 1979. B. Ezell. SML 7447. All verified by Mark A. Paulissen. First parish records; expands the distribution of this species westward from Lafayette Parish as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.) and from St. Landry Parish as recorded by Vidrine and Hatler (1995, Herpetol. Rev. 26:155). It is unclear when this population was introduced into the University area. Regardless, it has since become very common throughout the city of Lake Charles and the surrounding communities (Williams, pers. obs.). AVOYELLES PARISH: Eola area. March 1963. W. Simpson and J. G. Walls. SML 271. Verified by Mark A. Paulissen. First parish record as mapped by Dundee and Rossman (*op. cit.*); expands the distribution of this species northeastward from Evangeline Parish as recorded by Boundy (1994, Herpetol. Rev. 25:128–129).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: BOSQUE CO: Valley Mills, ca 10 mi W of Clifton. 7 July 1996. C. J. Franklin and S. M. Franklin. University of Texas at Arlington Collection of Vertebrates (UTA-R 40734). Verified by C. L. Stewart. New county record. (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **CARL J. FRANKLIN**, Department of Herpetology, Dallas Zoo, 650 South R. L. Thornton Freeway, Dallas, Texas 75203, USA.

HOMONOTA ANDICOLA (NCN). ARGENTINA: LA RIOJA: Las Chacritas, 33 km W Alto Jagüé, Department General Lamadrid. 10 February 1997. Sebastián E. Torres. Fundación Miguel Lillo, Tucumán, Argentina (FML 6101). Verified by Fernando Lobo. First record for La Rioja Province; extends range north 400 km (airline). Species was previously known only from the Uspallata region in Mendoza Province (Cei 1978, Publ. oc. Inst. Biol. an. Univ. nac. Cuyo 1:1–2).

Submitted by **SEBASTIAN E. TORRES**, **VIRGINIA ABDALA,** and **SONIA KRETZSCHMAR**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000, Tucumán, República Argentina.

LACERTA VIRIDIS (Green Lacerta). USA: KANSAS: SHAWNEE CO: Topeka, 4420 SW 23rd Street. 2 August 1996. Jerry Jones. KU Color Slide 11235. Verified by Joseph T. Collins. Species was originally documented as introduced via a commercial animal dealer in Topeka by Collins (1974, Amphibians and Reptiles in Kansas. First Ed. Univ. Kansas Nat. Hist. Mus. Pub. Ed. Ser. 1:1–283) and again by Collins (1983, Amphibians and Reptiles in Kansas. Second Ed. Univ. Kansas Nat. Hist. Mus. Pub. Ed. Ser. 8:1–356), based on specimens taken in 1973 and 1977, respectively. Because no documented vouchers were discovered after 1977, Conant and Collins (1991, Peterson Field Guide to Reptiles and Amphibians Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston. 450 pp.) did not consider this lizard established in the United States.

The specimen reported herein is the first collected in 19 years, and documents the continued presence of *L. viridis* in the Topeka area. The lizard was caught ca. 500 m from the source of the original introduced population, and is currently being maintained alive by Jim Gubanyi. Upon its death, the lizard will be deposited in the University of Kansas Natural History Museum, Lawrence.

Submitted by **JAMES GUBANYI**, 2501 Burnett Road, Topeka, Kansas 66614, USA, and **JOSEPH GUBANYI**, Concordia College, 800 North Columbia, Seward, Nebraska 68434, USA.

LIOLAEMUS FITZGERALDI (Lagartija del Aconcagua). CHILE: IV REGION—Coquimbo: Las Gualtatas, near copper mine Los Pelambres, 55 km west Illapel (31°38'S, 71°10'W). 6 January 1997. L. J. Avila and E. Soto. Herpetological collection, Orientación Zoología de Vertebrados, Departamento de Ciencias Naturales, Universidad Nacional de Río Cuarto, Argentina (ZV-UNRC 4066–68). Verified by R. A. Martori. First record for IV Región—Coquimbo (Veloso and Navarro 1988, Boll. Mus. Reg. Sci. Nat. Torino 6[2]:481–539; Nuñez and Jaksic, 1992. Bol. Mus. Nac. Hist. Nat. Chile, 43:63-91). The locality reported here is at ca. 3300 m elevation; extends range nearly 150 km N from type locality at Puente del Inca, Dpto. Las Heras, Mendoza (Argentina).

Submitted by **LUCIANO JAVIER AVILA**, Departamento de Ciencias Naturales, Universidad Nacional de Río Cuarto, Agencia Postal Nro. 3, C.P. 5800, Río Cuarto (Córdoba), Argentina (e-mail: lavila@exa.unrc.edu.ar), and **EDUARDO SOTO**, Zoología de Vertebrados, Facultad de Ciencias, Universidad de Chile.

LIOLAEMUS SAXATILIS (NCN). ARGENTINA: SAN LUIS: Dept. Coronel Pringles:10 km W La Toma (33°04'S, 65°38'W), Ruta Provincial 10, near Sierras del Rosario. 5 October 1996. Herpetological collection of Orientacisn Zoologma de Vertebrados, Departamento de Ciencias Naturales, Universidad Nacional de Rmo Cuarto, Argentina (ZV-UNRC 3968); same locality. 8 December 1996. ZV-UNCR 4022; 28 km SW La Toma (near Ruta Provincial 20). 8 December 1996. ZV-UNRC 4023–24. All collected by L. J. Avila, J. W. Priotto and M. Morando, and verified by Ricardo A. Martori. First province records; a westward extension of the known range ca. 75 km from type locality (Avila et al. 1992, Bol. Mus. Reg. Sci. Nat. 10[1]:101–111).

Submitted by **LUCIANO JAVIER AVILA**, **JOSE W. PRIOTTO,** and **MARIANA MORANDO**, Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Estafeta Postal 9, C.P. 5800, Rio Cuarto, Cordoba, Argentina. E-mail (LJA): lavila@exa.unrc.edu.ar

NOROPS PACHYPUS (Thick Anole). COSTA RICA: GUANACASTE PROVINCE: Guanacaste Conservation Area, Las Pailas Sector, E side of Laguna Jilgueros at the crest of Rincón de la Vieja Volcano, 1526–1537 m elev., 10°50'N, 85°22'W). 17 June 1995 and 11 August 1996. David T. Nicolson, Jason D. Johnson, and Kirsten E. Nicholson. University of Miami Costa Rican Expeditions (CRE 7612–7618, 10392). Verified by Jay M. Savage. Extends known range ca. 157 km airline NW of Alto del Roble and ca. 10 km N of Barba, Heredia Province (CRE 7094 collected by J. M. Savage and N. Scott; Savage and Villa 1986, Herpetofauna of Costa Rica, Contributions to Herpetology No. 3). We also have examined specimens of this taxon (previously identified as *Norops tropidolepis;* verified by Jay M. Savage) collected from Volcan Cacao, 1590–1600 m elev., 10°56'N, 85°27'W, on 3 and 24 August 1987 (MVZ 207349–51). These additional specimens extend the previous known range 176 km airline NW from Alto del Roble.

Submitted by **KIRSTEN E. NICHOLSON** and **DAVID T. NICOLSON**, Department of Biology, University of Miami, Coral Gables, Florida 33124, USA.

OPHISAURUS ATTENUATUS LONGICAUDUS (Eastern Slender Glass Lizard). USA: GEORGIA: BULLOCH CO: SR 1838, 6.4 km N SR 1838/Georgia Rt. 321 jct. (1.6 km N Bulloch-Bryan county line). 7 May 1994. Collector not recorded. Savannah Science Museum (SSM 96.13765). Verified by Robert A. Moulis. New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Publ. 3:1–712). Specimen was caught crossing SR 1838 at ca. 1630 h.

Submitted by **MICHAEL G. FRICK**, Savannah Science Museum, 4405 Paulsen Street, Savannah, Georgia 31405, USA.

PHYLLODACTYLUS XANTI (Cape Leaf-toed Gecko). MÉXICO: BAJA CALIFORNIA SUR: Isla Pardo, one of five islands in a group collectively known as Islas Los Candeleros, located SW of Isla Danzante in the vicinity of Loreto (Crumpton 1991, Baja Explorer: Topographic Atlas Directory. ALTI Publishing, La Jolla, California; Williams 1988, Baja Boater's Guide: Volume II—Sea of Cortéz. H. J. Williams Publications, Sausalito, California. p. 151). 22 March 1996. L. Lee Grismer, Bradford D. Hollingsworth, Humberto Wong, and Michael R. Cryder. La Sierra University Photographic Collection (LSUPC L3026). Verified by Lester E. Harris. First record for Isla literature (Murphy and Ottley 1984, Ann. Carnegie Mus. Nat. Hist. 53:207–230). Specimen was found during the day beneath a pile of rocks on the cobblestone beach.

Submitted by **MICHAEL R. CRYDER**, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA, and Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, **BRADFORD D. PODARCIS ERHARDII LIVADIACA (Erhard's Wall Lizard). GREECE: STEREA ELLADA: AETOLOACARNANIA PREFECTURE: NAFPACTIA CO: 2.3 km NE Stylia, 700 m elev. (38°30'19"N, 21°48'38"E). 28 November 1996. George Chiras and Basil P. Chondropoulos. Zoological Museum of University of Patra (ZMUP A-R 1375). Verified by E. Valakos. An adult male; 4–5 more individuals were observed basking on the banks of a road crossing a dense Hungarian oak (*Quercus conferta*) forest. *Podarcis erhardii* is a southern Balkan endemic species; in Greece it occurs in parts of the mainland and in the western and south Aegean islands. Prior to this discovery, there has been a complete lack of data concerning the species distribution in the central and western Sterea Ellada region. The nearest previous record was ca. 120 km NW in the Epirus region (Gruber 1986, *In* W. Böhme, ed., Handbuch der Reptilien und Amphibien Europus, pp. 25–49. Aula-Verlag, Wiesbaden). At the subspecies level, the known range of *P. e. livadiaca* covers only the eastern part of Sterea Ellada (Attiki and Evia Prefectures) and the eastern part of Peloponnisos region (Wettstein 1953, Sitz.-ber. Österr. Akad. Wiss. Wien 162:651–833; Chondropoulos 1986, Amphibia-Reptilia 7:217–235). This record extends considerably both the species and subspecies ranges, filling a very large distributional gap for this lizard in the western Greek mainland.

Submitted by **BASIL P. CHONDROPOULOS**, Section of Animal Biology, Department of Biology, University of Patra, 260 01 Patra, Greece, and **GEORGE CHIRAS**, Sarantaporou 38, 262 23 Patra, Greece.

SCINCELLA LATERALIS (Ground Skink). USA: ALABAMA: WINSTON CO: William B. Bankhead National Forest, ca 1.5 km NE Adkins Cemetery. N 1/2 Sec. 16, T9S, R8W. 5 October 1996. AUM 34303. Verified by Craig Guyer. New county record (Mount 1975, The Reptiles and Amphibians of Alabama. Publ. Alabama Agric. Exp. Sta., Auburn. 347 pp.).

Submitted by **BRIAN P. BUTTERFIELD**, **DANIEL R. FRENCH**, **SCOTT R. FEARS**, **MICHELLE D. HARGREAVES**, **ANGELA J. LEWIS**, **CHRISTINE D. ROBY**, **LEAH M. HOOD**, and **JENNIFER R. ROBINSON**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

SERPENTES

CROTALUS WILLARDI OBSCURUS (New Mexico Ridgenose Rattlesnake). USA: ARIZONA: COCHISE CO: Sec. 14, T22S, R32E. 24 October 1996. Sam W. Smith. AMNH 142597. Verified by Michael Douglas. State record for this federally threatened subspecies. Found on leaf litter in canyon bottom dominated by oaks, alligator bark juniper, and Mexican pinyon. Collected under permit to Andrew T. Holycross (U.S. Fish and Wildlife Service PRT676811 and Arizona Game and Fish Department SP648632) and euthanized under permit to the Arizona Game and Fish Department (U.S. Fish and Wildlife Permit PRT676811).

Submitted by **ANDREW T. HOLYCROSS**, Department of Zoology, Arizona State University, Tempe, Arizona 85287-1501, USA, and **SAM W. SMITH**, 4338 East Elmwood Street, Tucson, Arizona 85711, USA.

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake) USA: OHIO: MAHONING CO: Canfield Township: DOR on Turner Road, 1 mi N Palmyra Road. 4 July 1995. Raymond J. Novotny. Cleveland Museum of Natural History 6760. Verified by Timothy O. Matson. First county record; fills range gap between Trumbull County to N, Columbiana County to S, Portage County to W, and Lawrence County, Pennsylvania to E as depicted in Conant (1951, Reptiles of Ohio. 2nd ed. [with revisionary addenda], Amer. Midl. Nat., Univ. Notre Dame, Indiana. 284 pp.) and McCoy (1982, Amphibians and Reptiles in Pennsylvania. Carnegie Mus. Nat. Hist., Pittsburgh, Pennsylvania. 91 pp.).

Submitted by **RAYMOND J. NOVOTNY**, Ford Nature Center, Mill Creek Metropolitan Park District, 840 Old Furnace Road, Youngstown, Ohio 44511, USA.

ELAPHE OBSOLETA SPILOIDES (Gray Rat Snake). USA: GEORGIA: TIFT CO: S2516, 2.08 km S S2516/Georgia Rt. 35 (US Rt. 319) jct. (11.2 km NNE Tifton). 28 September 1996. J. Andrew Jackson. Savannah Science Museum (SSM 96.13764). Verified by Michael G. Frick. New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Pub. 3:1–712). Specimen was caught crossing highway at ca. 1430 h.

Submitted by **J. ANDREW JACKSON**, Savannah Science Museum, 4405 Paulsen Street, Savannah, Georgia 31405, USA.

HAEMORRHOIS* (= *COLUBER*) *DORRI (Boie's Racer). SENEGAL: SENEGAL ORIENTAL REGION: Bandafassi (12°32'N, 12°18'W). 28 December 1989. Jean-François Trape. Museum National d'Histoire Naturelle at Paris (MNHN-

1995.9693). Verified by Ivan Ineich. First regional record and second for Senegal. Extends range 260 km southward from the closest known locality at Bakel, Upper Senegal, where the type originated (Lataste 1888, Le Naturaliste, 10:227–228). This species is also known from Mali, Burkina-Faso, Ghana, and Togo (Villiers 1975, Les Serpents de l'Ouest Africain, Institut Fondamental d'Afrique Noire, Initiations et Etudes Africaines n °2, 3éme edition, Dakar, 195 pp.).

Submitted by **JEAN-FRANCOIS TRAPE**, Laboratoire de Paludologie, ORSTOM, P.O. Box 1386, Dakar, Sénégal.

LEPTOPHIS AHAETULLA MARGINATUS (Parrot Snake). URUGUAY: DEPARTAMENTO DE ARTIGAS: Arrocera San Pedro, 25 km W of Colonia Palma. Between October 1983 and January 1984. ZVC-R 4401, 4529–30, and MNHNM 3740. First vouchers for Uruguay, substantiating an earlier literature record of *Leptophis liocercus* (Wied, 1824) (= *Leptophis ahaetulla marginatus*) by Koslowsky (1898, Rev. Mus. La Plata 8:164, 191) (*contra* statement by Peters and Orejas-Miranda 1970, Bull. U.S. Natl. Mus. 299:viii + 347).

Submitted by **MELITTA D. MENEGHEL** and **FEDERICO ACHAVAL**, Seccion Zoologia de Vertebrados, Instituto de Biologia, Facultad de Ciencias, Tristan Narvaja 1674, Casilla de Correos 10.773, 11.200 Montevideo, Uruguay.

PORTHIDIUM HESPERE (Western Hognose Viper). MÉXICO: MICHOACAN: Municipality of Aquila: Playa Colola (18°18'00"N, 103°21'00"W, sea level) 4 November 1995. R. Nuñez-Pérez and C. Delgadol-Trejo. Facultad de Biología, Universidad Michoacana de San Nicolás de Hidalgo (FBH 0239). Verified by Gustavo Casas-Andreu. Adult female (245 mm SVL; 70 mm TL) collected at 2345 h on an *Acacia* tree. This species was known definitely only from the type locality, 19.2 airline km NE Tecomán, Municipality of Ixtlahuacán, Colima, and description was based on a single specimen (Campbell 1976, J. Herpetol. 10:151–160). Huacuz (1995, Serpientes del Estado de Michoacán, Master's Thesis, Univ. Nac. Autón. de México), recently reviewed the ophidiofauna of Michoacán, and predicted the presence of this snake in the state. First documented record for the state of Michoacán and extends its known range ca. 95 km SE of type locality.

Submitted by **JAVIER ALVARADO-DIAZ, DOLORES DEL C. HUACUZ-ELIAS** and **IRERI SUAZO-ORTUÑO**, Facultad de Biología, Universidad Michoacana, Apartado 35-A, Morelia 58000, Michoacán, México.

PSEUDOTOMODON TRIGONATUS (False Tomodon Snake, Culebra Enhebrada). ARGENTINA: CORDOBA: DEPARTAMENTO CALAMUCHITA: bridge over Guacha Corral Creek, 15 km W Río de los Sauces (town) (32°32'S, 64°36'W). 11 April 1993. L. J. Avila. Colección de Vertebrados Universidad Nacional de Río Cuarto (ZV-UNRC 2342); DEPARTAMENTO RÍO CUARTO: 2 km E El Chacay village (32°53'S, 64°50'W). 19 October 1991. R. Martori and L. Aun. ZV-UNRC 1607; Achiras (33°10'S, 64°59'W). 4 November 1990. L. J. Avila and P. Pettinicchi. ZV-UNRC 1213–15; Alpa Corral (32°52'S, 64°57'W). 14 March 1995. M. Arana. ZV-UNRC 3611. All verified by Ricardo A. Martori. First vouchered records from the province of Córdoba. Previous citations (Cei 1986, Mon. IV. Mus. Reg. Sci. Nat. Torino. 527 pp.; Cei 1993, Mon. XIV Mus. Reg. Sci. Nat. Torino. 949 pp.; Williams and Francini 1991, Boll. Mus. Reg. Sci. Nat. 9[1]:55–90) were unvouchered (Reati 1996, *In:* Biodiversidad de la Provincia de Córdoba. Di Tada and Bucher, eds. pp. 239–254).

Submitted by **LUCIANO JAVIER AVILA**, Departamento de Ciencias Naturales, Universidad Nacional de Río Cuarto, Agencia Postal 3, C. P. 5800, Río Cuarto (Córdoba), Argentina. E-mail: lavila@exa.unrc.edu.ar.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). FEDERATED STATES OF MICRONESIA: CAROLINE ISLANDS: POHNPEI STATE: Pohnpei Islands, Uh Municipality, Mwahnd Peidi Island, Station 56, 3–30 m elev. (Mwahnd Peidi Island is ca. 158°17'E, 6°40'N of the main island of Pohnpei.) 22 July 1995. Don Buden. First island record. MCZ 180888. Verified by Van Wallach. Closest locality is "Ponape, Caroline Islands" (McDowell 1974, J. Herpetol. 8[1]:1–57). McDowell's locality is unclear because "Ponape" (= Pohnpei) could refer to either the State or the island.

Submitted by **LESLIE A. THOMAS**, Center for Vertebrate Studies, Department of Biology, Northeastern University, Boston, Massachusetts 02115, USA.

REGINA GRAHAMII (Graham's Crayfish Snake). USA: LOUISIANA: CALCASIEU PARISH: 6.3 mi S and 3.6 mi E Lake Charles on Lincoln Road. 15 March 1972. R. LeBoeuf. Seale Museum of Louisiana, McNeese State University (SML 4953); 2 mi W jct. Louisiana Rt. 108 and Louisiana Rt. 27. 4 February 1973. M. Dugas. SML 5556; 10 mi E and 6 mi S Lake Charles. 27 February 1974. J. Dolan. SML 6196; 12 mi W and 6 mi S Lake Charles, Choupique Bayou area. 2 March 1974. P. Rider. SML 6285; 2 mi S of I-210 on Louisiana Rt. 14. 13 April 1985. T. Broussard. SML 8288; 0.5 mi N Sulphur. 28 March 1985. Smith and Nichols. SML 8354; 11 mi NW Vinton. 23 March 1991. H. Abner and R. Heiner. SML 9191; 1 mi W jct. of Louisiana Rt. 379 (Houston River Road) and Clairborne Street, Houston River Canal area. 17 March 1993. Avery A. Williams. SML 9303 (Specimen was collected while it was copulating in a flooded right-of-way clearing. Its mate escaped collection.); JEFFERSON DAVIS PARISH: 1 mi N and 1.7 mi E Hayes, Lorrain Park area. 24 March 1971. D. Fruge. SML 5144. All verified by Douglas A. Rossman. First parish records; extends distribution north from Cameron Parish as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.)

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

REGINA RIGIDA (Glossy Crayfish Snake). USA: LOUISIANA: CALCASIEU PARISH: 1 mi N and 0.9 mi E Bell City. 24 March 1972. D. Fruge. Seale Museum of Louisiana, McNeese State University (SML 4965); 0.8 mi N and 0.4 mi E Bell City. 22 June 1971. D. Fruge. SML 5154; 2 mi N Bell City. 31 March 1973. C. Hudson. SML 5522; 2 mi N Bell City. 31 March 1973. G. Bauer. SML 5581; 1 mi S jct. Lincoln Road and Nelson Road, Hippolyte Coulee area. 14 February 1974. D. Guillory. SML 6330; 2 mi N and 2 mi W Moss Bluff, Bunker Hill Canal area. 30 January 1986. Doyle, Ester, and Thompson. SML 8503; 1 mi N jct. Louisiana Rt. 378 and North Perkins Ferry Road, Moss Bluff area. 3 November 1987. Walther, Tietje, and Russo. SML 8688; NW of Westlake, 1 mi N jct. of John Stine Road and Myrtle Springs Road on May Street (two specimens collected from roadside ditches by neighborhood children using pellet guns). 30 March 1996. Avery A. Williams. SML 9301–02. All verified by Douglas A. Rossman; expands the distribution of this species in Calcasieu Parish from the single record mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

VIRGINIA VALERIAE (Smooth Earth Snake). USA: KANSAS: Miami Co: 0.5 km S & 4 km E of Fontana, border of SE 1/4 of SE 1/4 Sec. 6, and SW 1/4 of SW 1/4 Sec. 5, T19S, R24E. 28 April 1996. Eric M. Kessler. KU 223467. Verified by Joseph T. Collins. New county record (Collins 1993, Amphibians and Reptiles in Kansas, Univ. Press Kansas, Lawrence. xx + 397 pp.).

Boulder, Colorado 80309-0218, USA
e-mail: hsmith@spot.colorado.edu

The following nine specimens represent new distributional records for amphibians and reptiles in Texas, and increase our knowledge of the biology of the herpetofauna of that state. WTAMU = herpetological collection at West Texas A&M University, Canyon, Texas.

Ambystoma tigrinum tigrinum (Eastern Tiger Salamander). USA: TEXAS: Angelina Co: 4.8 km N Lufkin, Rt. 81. 18 September 1993. Kyla A. Murdick. WTAMU 14934. Verified by Anthony I. Mazeroll. First county record (Dixon 1987).

Hyla chrysoscelis (Cope's Gray Treefrog). USA: TEXAS: Aransas Co: Fulton. 16 April 1992. J. Culwell. WTAMU 14473. Verified by Anthony I. Mazeroll. First county record (Dixon 1987). An adult 38 mm SVL, with spotted throat, irregular marks on dorsum, rear surface of thigh unmarked.

Rana blairi (Plains Leopard Frog). USA: TEXAS: Moore Co: Plum Creek behind camp. 22 October 1994. J. J. Rinne. WTAMU 14951. Verified by Anthony I. Mazeroll. First county record (Dixon 1987).

Xenopus laevis (African Clawed Frog). USA: TEXAS: Llano Co: Lake Buchanan. 10 April 1981. Stacey Foster. WTAMU 6266. Verified by Anthony I. Mazeroll. Not previously reported from the state (Dixon 1987). Taken by a student on a class trip for a field course, cataloged in that student's field notes, and there identified as *Gastrophryne,* an expected species, hence given no special attention at the time. No other details of discovery known.

Hemidactylus turcicus (Mediterranean Gecko). USA: TEXAS: Comal Co: Canyon Lake at Kelly Air Force Base Recreation Area. 11 November 1995. J. A. Jesko. WTAMU 15025. Verified by Anthony I. Mazeroll. First county record (Dixon 1987).

Coluber constrictor flaviventris (Eastern Yellowbelly Racer). USA: TEXAS: Hardeman Co: Rt. 1167, Medicine Mound Ranch. 16 May 1995. Kathleen B. Blair. WTAMU 15036. Verified by Anthony I. Mazeroll. First county record (Dixon 1987).

Elaphe guttata emoryi (Great Plains Rat Snake). USA: TEXAS: Wheeler Co: 6.5 km NE Shamrock. No date. Derl Brooks and H. H. Bailey. WTAMU 15006. Verified by Anthony I. Mazeroll. First county record (Dixon 1987).

Elaphe obsoleta lindheimerii (Texas Rat Snake). USA: TEXAS: Hardeman Co: Rt. 1167, Medicine Mound Ranch. 16 May 1995. Kathleen B. Blair. WTAMU 15035. Verified by Anthony I. Mazeroll. First county record (Dixon 1987).

Heterodon platirhinos (Eastern Hognose Snake). USA: TEXAS: Oldham Co: Boys Ranch Hog Farm, Boys Ranch. 9 July 1991. Eddie Taylor. WTAMU 14404. Verified by Anthony I. Mazeroll. First county record, at the western edge of the species' range (Dixon 1987).

New Records for Amphibians and Reptiles from Texas

HOBART M. SMITH
Department of EPO Biology, University of Colorado
Boulder, Colorado 80309-0334, USA
e-mail: hsmith@spot.colorado.edu

and
DAVID CHISZAR
Department of Psychology, University of Colorado
Boulder, Colorado 80309-0345, USA
e-mail: chiszar@cliper.colorado.edu

A review of amphibians and reptiles from Texas in the University of Kansas Museum of Natural History has revealed the following county records, as indicated by our updated copy of Dixon's (1987) summary, of six taxa, and a presumably erroneous record that may be of historical interest for one other taxon. Joseph Mendelson III kindly verified all except the material of *Scaphiopus*, which is unverifiable.

Bufo americanus charlesmithi (Dwarf American Toad). USA: TEXAS: Panola Co: Sabine River, N Carthage. 5 April 1961. Frank B. Cross. KU 70013.

Syrrophus marnockii (Cliff Chirping Frog). USA: TEXAS: Bandera Co: km W Medina. 4 May 1957. James R. Dixon. KU 60243. 21 km W Medina 4 May 1957. James R. Dixon. KU 60242. 9.7 km NM Medina, Keese Cave. 11 July 1974. No collector. KU 159614.

Scaphiopus holbrookii hurterii (Hurter's Spadefoot). USA: TEXAS: Dewitt Co: 8 km S Yoakum. 23 April 1963. C. M. Fleming. KU 186982. Serial sections of skull only (no body).

Sceloporus serrifer cyanogenys (Blue Spiny Lizard). USA: TEXAS: Hidalgo Co: Lower Rio Grande Valley National Wildlife Refuge, Sam Fordyce Tract. June 1992. Richard Courtemanche. KU 222526.

Salvadora grahamiae lineata (Texas Patchnose Snake). USA: TEXAS: Willacy Co: 6.3 km E Porfirio. 28 August 1992. Kelly J. Irwin. KU 222583.

Crotalus viridis viridis (Prairie Rattlesnake). USA: TEXAS: Coke Co: 9.7 km N Water Valley. 2 January 1959. Paul Anderson. KU 84554.

Gopherus berlandieri (Texas Tortoise). USA: TEXAS: Callahan Co: Putnam. 9 June 1926, 9 July 1926, 10 September 1927, 18 September 1927. No collector. KU 2674–5, 3003–9, 3011–2, 5037–9, and 6871. These specimens, from some 300 airline km to the north of the range limits of the species as now known, were obtained from A. J. Kirn, who lived near Somerset, Atascosa County, Texas, where the species is known to occur. Kirn collected many reptiles and amphibians in the county for several museums, through various specialists including E. H. Taylor and Howard K. Gloyd, and would not likely falsify data. Possibly these specimens were given to him with erroneous locality data, inasmuch as he did not record himself as collector.

The Northern Alligator Lizard (*Elgaria coerulea*) from Nevada

JENS V. VINDUM
Department of Herpetology, California Academy of Sciences Golden Gate Park, San Francisco, California 94118-4599, USA

and

E. N. ARNOLD
Department of Zoology, Natural History Museum, London SW7 5BD, United Kingdom

Banta (1964) summarized the early herpetological works on reptiles of the Great Basin in the western United States. Although some of these works were fairly comprehensive (Linsdale 1940), no anguid species were reported from the state of Nevada. Banta (1965) anticipated the occurrence of *Elgaria coerulea* in the Lake Tahoe region of Nevada and *E. panamintina* in the Palmetto Mountains, Esmeralda County, Grapevine Mountains, Nye County, and Spring Mountains, Clark County. *Elgaria multicarinata* was introduced to the Las Vegas area (Stebbins 1985) and a voucher specimen exists for this region (Nevada: Clark Co: Las Vegas. 13 June 1959. G. Ferske. Marjorie Barrick Museum, University of Nevada, Las Vegas [MBM] 43). A second known specimen of *E. multicarinata* was recently seen in southern Nevada (Nevada: Clark Co: Lake Mead National Recreation Area, Boulder Beach Campground. 4 April 1993. W. Pratt [pers. comm. A. Heindl 1996]) but was not collected.

Herein we report on three unpublished records of naturally occurring *Elgaria coerulea* from northern Nevada. The identifications were verified by Christopher J. Bell (Museum of Paleontology, University of California, Berkeley).

NEVADA: Carson City Co: at the point where Clear Creek crosses US Rt. 50 (T15N, R19E Sec. 32). 1 July 1993. B. Cobb. MBM 7444. This specimen extends the range of *E. coerulea* to the eastern side of the Lake Tahoe basin.

NEVADA: Washoe Co: Sheldon Antelope Refuge, Badger Mountain, Badger Cabin. Summer 1960. O. V. Deming. MBM 447.

NEVADA: Washoe Co: Upper High Rock Canyon, 41°29'25.4"N, 119°29'53.8"W, SE 1/4 of SE 1/4 Sec. 4, T41N, R22E, 1754 m. 11 June 1996. E. N. Arnold and J. V. Vindum. CAS 201283. Upper High Rock Canyon is about 2 km in length with steep walls reaching heights of ca 100 m above the canyon floor. In most areas the base of the canyon is less than 50 m wide. The area surrounding the canyon and extending to the base of the canyon consists of sagebrush steppe. Aspen riparian forest is the dominant plant community along the length of the canyon floor. The specimen was found ca. 5 m from the creek bed in a small grassy glade between the riparian and sagebrush plant communities.

Based on Lais (1976), Stebbins (1985), and Brown et al. (1995), these two Washoe County specimens represent the third and fourth isolated populations of *Elgaria coerulea* found in the western Great Basin. The other two isolated populations are: 1) in the Warner Mountains (California: Modoc Co: Ft. Bidwell-Adel Hwy, Twelve Mile Creek at Oregon state line. 3 July 1934. H. S. Fitch. MVZ 17218-21; Fitch [1938] cited the locality as "Twelve-mile Creek, Modoc Co., Calif. at Nevada line"), and 2) in the Hart Mountains (Oregon: Lake Co: Desert Lake, Water Canyon, 22.5 km SE of Hart Mountain Wildlife Refuge Headquarters. 25 August 1954. C. Nelson. OS 2934. Oregon: Lake Co: about 91.4 m above the mouth of Water Canyon, W of Desert Lake, Hart Mountain National Wildlife Refuge. 8 July 1960. J. L. Richardson and T. Urbanek. OS 7673).

Although no late Pleistocene and Holocene fossil anguids have been found thus far in the Great Basin (Mead and Bell 1994), the four isolated populations suggest that *E. coerulea* was once more widely distributed in the western Great Basin. The current distribution seems now to be restricted to isolated populations in more mesic habitats.

Acknowledgments.—We thank T. A. Atkinson, C. J. Bell, D. B. Hardenbrook, A. L. Heindl, P. A. Medica, J. A. Rodriguez-Robles, and R. M. Storm for their assistance.

Florida is colonized by nine anoline lizards: *Anolis carolinensis* (Cope 1900), *A. chlorocyanus* (Bartlett 1988; Butterfield et al. 1994), *A. cristatellus* (Schwartz and Thomas 1975), *A. cybotes* (Ober 1973), *A. distichus dominicensis* (King and Krakauer 1966), *A. d. floridanus* (Smith and McCauley 1948), *A. equestris* (Neill 1957), *A. garmani* (Wilson and Porras 1983), and *A. sagrei* ssp. (Garman 1887). Only *A. carolinensis* and, arguably, *A. d. floridanus* are native. Among the exotic species, two, *A. equestris* and *A. sagrei*, are native to Cuba (Schwartz and Henderson 1991). *Anolis equestris* exploits the canopy and large branches of trees (Collette 1961) and fits the crown giant ecomorph (Williams 1969), whereas *A. sagrei* lives closer to the ground (Collette 1961) and fits the trunk-ground ecomorph (Williams 1969).

The Cuban green anole (*Anolis porcatus*), widespread in Cuba and sympatric with the former two species (Schwartz and Henderson 1991), is associated with the trunk and canopy (Collette 1961) and fits the trunk-crown ecomorph (Williams 1969). Only one record exists of a colony of *A. porcatus* outside of Cuba. *Anolis porcatus* was introduced to a site in the Dominican Republic probably in the 1950s where it has since expanded its geographic range by approximately 2.2 km^2 per year (Powell et al. 1990). This species was not introduced to Hawaii (McKeown 1996) as previously reported (McKeown 1978). Here, we record the presence of *A. porcatus* in Florida and relate data on diet and habitat to its structural niche in the introduced site.

A series of 12 males, 5 females, and 1 juvenile (Everglades Series: EVER 302589–302594, 302938–302940, 302947–302955) of *Anolis porcatus* was collected from buildings and vegetation in North Miami, Dade County, Florida on the afternoon of 13 and 16 June and 12 July 1996. All specimens were stored in the Everglades Regional Collections Center, Everglades National Park, Homestead, Florida. A male (EVER 302955) and female (EVER 302593) from that series were identified as *A. porcatus* by R. W. Henderson. This colony is approximately five years old and younger than a nine-year old colony in South Miami (Ron and Stella St. Pierre, pers. comm.) for which we have observations (reports) but no records. Derivations of both colonies are unknown.

The mean snout length (SVL) of male *Anolis porcatus* (66.2 ± 6.47 mm SVL; range = 55–76) was significantly larger ($Z = 19.94$, $P < 0.000$) than that of females (55.6 ± 6.83 mm SVL; range = 48–65). Number of prey from which length could be measured was too small to compare between sexes; however, prey were generally small (4.04 ± 4.59 mm; range = 1–23; N = 21) and the largest two items, an *A. sagrei* (23 mm SVL) and scarab beetle (10 mm) were found in two large males (68 and 73 mm SVL, respectively). Including even potentially adventitiously ingested items such as stones and fruit, a wide range of prey categories (N = 24) were found in the diet of *Anolis porcatus* (Table 1). However, for all lizards, Levins' measure of niche breadth (Levins 1968) was narrow as measured by frequency of prey (0.28) and number of stomachs common to each taxon (0.34). Prey, typically found in vegetation (e.g., ladybird beetles, weevils, caterpillars, stinkbugs, parasitic wasps) or not restricted to the ground (e.g., ants), reflected the location of the lizards, which were captured and observed from 1.0–6.0 m above the ground. In light of its sympatry in North Miami with *A. equestris* and *A. sagrei*, the structural position of *A. porcatus* at this site was in keeping with that of Cuban populations.

TABLE 1. Diet of *Anolis porcatus* from North Miami Beach, Broward County, Florida, USA. Number of prey are followed in parentheses by number of stomachs with each prey category.

Taxa	Males (N = 12)	Females (N = 5)	Juveniles (N = 1)	Total

This record of *Anolis porcatus* increased to seven the number of species of reptiles (*Anolis equestris, A. sagrei, Gonatodes albogularis, Sphaerodactylus argus, S. elegans)* and amphibians (*Eleutherodactylus planirostris, Osteopilus septentrionalis)* native to Cuba that are now established as probable exotics in Florida. Five of these species (*A. equestris, A. porcatus, A. sagrei, E. planirostris, O. septentrionalis)* are sympatric at the North Miami site—a noteworthy dimension to the colonization process whereby many elements of a single community have successfully translocated to a new site. Broad diet, familiarity with sympatric species, and persistent colonies, increase the likelihood that *A. porcatus* will succeed in other parts of extreme southern Florida. However, the ubiquity of its predator, *A. equestris,* far more numerous in Miami than in Cuba (Orlando Garrido, pers. comm.), could hinder the success of *A. porcatus* in southern Florida. We are especially concerned about the future of *A. porcatus* in Florida. Ability to

persist and the potential for future range expansion by this species in Florida could have a substantial and negative impact on its native ecological analog (*A. carolinensis)* much as it has had on *A. chlorocyanus* in a comparable situation in Santo Domingo, Dominican Republic (Powell et al. 1990).

Acknowledgments.—Ron and Stella St. Pierre kindly shared with us their knowledge of *A. porcatus* in Florida. Ron St. Pierre, Paul Bledsole, and the Auburn 1996 Summer Natural History of Vertebrates class assisted in the field. We thank Robert Powell for commenting on an earlier version of this paper.

BOOK REVIEWS

A Complete Guide to Scientific and Common Names of Reptiles and Amphibians of the World, by Norman Frank and Erica Ramus, 1995. NG Publishing, Inc., Pottsville, Pennsylvania, 377 pp. ISBN 0-9641032-3-0. US $19.95 (softcover).

WILLIAM W. LAMAR
School of Sciences and Mathematics, The University of Texas at Tyler

e-mail: 103223.306@compuserve.com

This book and two others (Sokolov 1988; Zhao et al. 1993) provide mute testimony to the burgeoning popularity of reptiles and amphibians around the world, not to mention the public's anxiety about scientific names. All three represent noble attempts at accomplishing a task that can only be described as thankless. Herpetologists and herpetoculturists are a rowdy and nonconsensual lot at best, and the some 10,000 species of herps, albeit sporting an impressive array of vernacular names, lack the stolid tradition with which the International Ornithologists' Union has managed to slap monikers on birds of the world. My brief foray into this contentious realm left me with the firm notion that only one kind of organism is suited to undertake naming the world's herps: the lemming.

The Frank and Ramus guide, which includes "12,000 species [and subspecies] organized taxonomically (by Order, Family, genus, species, plus subspecies for U.S. groups)," an index to genera, and an alphabetical index to common names, is by far the best book offered on the subject. That having been said, let me add that it is rife with errors of commission and omission, not to mention typographical blunders too numerous to cite. It is apparent that the authors were hampered not only by the formidable task but also by their lack of taxonomic training. Thus *Pliocercus elapoides* appears as the "Common False Coral Snake" or as the "Twin Coral Snake" under the genus *Urotheca*; species (...of *Anolis*, *Oxybelis*, and others) were omitted...one could continue.

An additional criticism, inescapable in books of this nature, is the abundance of cumbersome epithets. I have been accused of using flash cards at family reunions, so my credentials as a practitioner of common names are admittedly shaky. However comfortable I may be in the world of scientific nomenclature, I must confess to stark fear when contemplating the likes of the "Pulo Condore Bow-fingered Gecko." I struggle to contain my hysterics when I confront names like "Tumbo-Insel Screeching Frog," "Zong's Odd-scaled Snake," or "Pomugu Wrinkled Ground Frog." I get confused trying to visualize the "Thick Graceful Brown Snake" or the "Bearded Snake," and I feel intimations of British nobility when mouthing names like "Tilbury's Fringe Fingered Lizard" or "Palfreyman's Window-eyed Skink."

Levity aside, there are trenchant misnomers to be found: calling *Gymnophthalmus underwoodi* "Underwood's Spectacled Tegu" is a bit like calling *Draco volans* a pterodactyl. Of course, we routinely call them dragons, so perhaps I am being uncharitable. Let me repeat that this is a thankless task. Only fatigue and desperation could produce "Silverstone's Mushroomtongue Salamander," or the "Airstrip Caecilian" (its type locality), although I doubt I could invent names any better than the authors'. A more intimate knowledge of tropical geography might have presented a few more palatable names.

Frank and Ramus made every attempt to contact the scientific community and they used existing lists of common names wherever possible. But one must possess intimate knowledge of the field in order to weigh appropriately the systematic controversies that abound, and even established common name lists such as the one for the U.S. (Collins 1990) suffer from politics and ethnocentrism. Judging by the reference list, herpetocultural publications replete with names invented in the commercial animal trade were also consulted, a potentially dangerous practice.

The sad thing beneath the entire issue of common names is our collective fear of science and its nomenclature. It's an assailable stigma, but science lacks a publicist. Society routinely ingests Latin words like subpoena, oddities like xerox and kleenex, and even genera such as *Tyrannosaurus* and *Velociraptor*. Confronted with such an enormous list, it seems like it would be easier to stay with the existing scientific names. Should government or conservation agencies embrace this guide (perish the thought), scientists will have to purchase copies so they can look up the scientific names! If there is ever to be a workable and consensual common names list for herps, it will require the ongoing effort of a panel because the task remains...thankless.

ERNEST A. LINER
310 Malibou Boulevard
Houma, Louisiana 70364-2598, USA

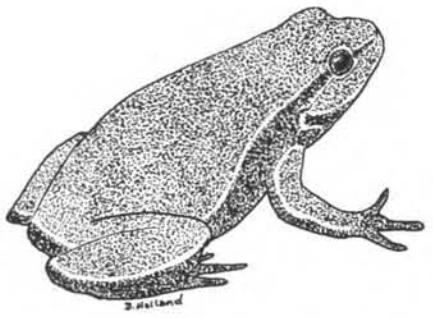
This 5 1/2 x 8 1/2 inch book is divided into three parts, an Index to Genera (11–19), a Taxonomic Section (23–261), and an Index to Common Names (265–369) of the reptiles and amphibians of the world. Species-level names are used except for U.S. taxa, which includes subspecies, thus comprising some 12,000 herps. The book is cross-referenced so that if the family, genus, species, or common name is known a given taxon can be located. The common name index is based on the assumption that the name you use is the one used in the book. This is a broad assumption inasmuch as common names exhibit little consistency. What is used in one area may not be used in another for the same animal. The authors have created common names for a large number of forms that have no English names.

As with any book of this type, it is outdated upon publication. Composition of genera and recognition of species change with increased information. Descriptions of new taxa occur frequently. This is what makes taxonomy such an exciting and evolving science. The U.S. and Canadian common names checklist (Collins 1990) and the recently-published Mexican checklist (Liner 1994) were utilized for North American taxa.

The inclusion of the generic index arranged alphabetically simplifies the location of where these taxa are in relation to their respective groups. The contents listing is helpful if you happen to know the family name for which you are looking, but I like the generic list better. The list would have been more useful if the describer and date of description of each genus was given. Although the authors do not indicate their cut-off date for inclusion of references, I found listings up through 1994.

For this review no effort was made to check out the accuracy of the taxonomic arrangements followed. I assume that this task was accomplished by the scientific reviewers listed in the acknowledgments. No statement is made about the criteria used to include or exclude a given taxon from the list, or to account for generic allocation of problematic species.

The authors state that they take credit or blame for this book. Typographic or spelling errors seem to be few for a work of such detail. A brief scanning of the pages revealed a missing date left on page 136. Among Mexican taxa, I noticed some duplicate listings: *Urotheca elapoides* Cope, 1860 and *Pliocercus elapoides* Cope, 1860; and *Barisia imbricata* Wiegmann, 1828 and *Gerrhonotus imbricatus* Wiegmann (no date). A careful check may turn up more errors of this type.



This book is not intended for the general layperson but for people interested in some form of herpetology, whether professional or amateur. The decision to put a common name on each and every species is an agonizing one. Many have no common name (at least not in English), while others have a multitude of names. The task of creating a meaningful common name is difficult. You are damned if you do and damned if you don't. Picking a single name for a taxon with a plethora of names is equally rough. You will not please everyone regardless of which name you choose and you cannot list all of them. As this book becomes more accepted, it can be periodically updated, as currently it is the most complete worldwide checklist of the herps. An impressive list of references (pp. 371–377) is given and I am sure others were consulted but not listed.

Although this book is not intended to be a coffee table item it is one that should be in every herpetologist's library. It is one that I will refer to often. The price is within the reach of most interested persons.

Caixa Postal 7172, São Paulo, Brazil

This book places in the hands of the working herpetologist the complete output of one of the most competent and prolific systematists ever, Wilhelm Peters of Berlin (1815–1883).

The Middle 19th Century witnessed an explosion of faunistic, and, by consequence, systematic knowledge. It was a time of intensive geographic exploration, both maritime and of the interior of the tropical continents, and the museums of the colonial powers grew commensurately. Their holdings were initially classified according to the canons of Linnaeus and early followers, but soon became the raw materials for the progress of systematic zoology. Wilhelm Peters was associated with the Berlin museum, one of the largest in Europe, from 1842 to his death in 1883. He occupied successively the positions of scientific assistant, curator, and director, but remained throughout essentially the curator of vertebrates.

The position of museum curator was in those days singularly active and diversified. There was very little, if any, specialization to zoological group or geographical area. It was the duty of the curator to structure, maintain, enlarge, and principally arrange the collections under his care, striving for completeness. This naturally involved research, but of an entirely unplanned character—the curator had simply to solve the problems posed by materials haphazardly received. This was the school of impromptu curatorship to which belonged, with greatness, Gabriel Bibron in Paris, George Albert Boulenger in London, and Wilhelm Peters in Berlin.

This type of curatorial activity unavoidably resulted in a mass of papers of circumstance: mostly accounts of collections donated, small and large, with the descriptions of new taxa, but also incidental items of anatomy, critiques of current literature, etc. In the beginning of his career, before a one-man, long expedition to East Africa (1842–1848), Peters, as a properly trained German zoologist, published nine papers: seven anatomical, one on a mite, and only one systematical. After his return from Africa, of 205 papers published eight referred to results of the expedition (including an important book), two dealt with reptilian systematics at the family level (Uropeltidae and Scincidae), and one with a South American lizard genus, *Cercosaura*. All the remainder are of the type I have called "of circumstance," determined by hazard, not by intent.

This involves no slight to the scientific quality of the papers. Men of talent, with a solid scientific foundation (Peters studied under the elder Reinhardt in Copenhagen and under Johannes Müller in Berlin), having at their command extensive collections and the full bibliographic resources of the time, had to produce good quality. In fact, much of the progress of systematic zoology followed from papers of such a type; the works of ensemble (e.g. the Erpétologie Générale, the British Museum Catalogues) were essentially compilations of work published piecemeal. Practically two thirds of the ca. 650 new forms (species, subspecies, and varieties) proposed as new by Peters are currently considered valid.

The only criticism I see that can be raised against Peters's professionalism is a flagrant disregard for geography. Many species, for instance, are described as "angeblich" (allegedly) from such or such a country. In one paper (1871b) Peters professes to be describing a collection made in the "Hochlande" (highlands) of Perú; the five localities actually cited are all Amazonian.

Circumstantial papers demand prompt publication. Peters had recourse mostly to the Monatsberichte of the Berlin (Prussian) Academy of Sciences, which could take at times as little as one week to publish a (suitably laconic) paper. This journal is not frequent in modern libraries. Additionally, it contains numerous occasions for doubts and uncertainties, especially when available solely in the form of a xerographic copy of a single article. It is thus a tremendous contribution to the practice of herpetology to publish in an organized facsimile form the voluminous corpus of Wilhelm Peters's herpetology, which covers literally all the field and all the world.

The apparatus of the book consists of 1) an Introduction, dealing mostly with the Berlin museum; 2) a biography of Peters; 3) an introduction to Peters's bibliography; and 4) a definitive, annotated list of Peters's herpetological papers, settling all doubts. This first part of the book is authored by Aaron M. Bauer, Rainer Günther, and Meghan Klipfel, who must be complimented for a careful and meticulous piece of work, never descending into preciosity.

The large number and diversified size of the papers to be reproduced caused the page size to be large, 28.0 x 21.5 cm, with narrow margins; even so, many of the papers had to be reduced for reproduction. Nothing, however, has interfered with readability. The plates, reproduced from gray lithographs, are of course not vivid, but quite usable.

This is all in all a superb piece of work, of immeasurable practical value and extremely high intellectual standards. One recognizes the tradition of the SSAR and the editorial hand of Kraig Adler.

Amphibians and Reptiles of New Mexico, by William G. Degenhardt, Charles W. Painter, and Andrew H. Price. 1996. Illustrations by Clay M. Garrett. Foreword by Roger Conant. University of New Mexico Press, Albuquerque. xix + 431 pp. cloth, US $35.00 plus shipping. ISBN 0-8263-1695-6.

JAMES R. DIXON
705 Inwood Drive, Bryan, Texas 77802, USA

Both amateur and professional herpetologists should buy this book. The book is concise, well written, and covers the subject matter of New Mexico Herpetology. Besides the usual foreword, written by Roger Conant, preface, and acknowledgments, the book has a number of major headings: A physiographic sketch of New Mexico; A brief history of herpetology of New Mexico; A checklist of amphibians and reptiles; A key to the tadpoles and salamander larvae; A key to the salamanders; A key to the frogs and toads; A key to the turtles; A key to the lizards; and A key to the snakes. Following each key, there is a discussion of the various families to which the organisms belong. Each family description is followed by species accounts. The first line of the species account contains the scientific name, followed by authorship, date, and common name. The next line directs the reader to a color plate for that

species. There are 123 color plates that are grouped in the center of the book. Within the species accounts, there are a series of topics that thoroughly explain the authors viewpoints on each species. First, there is a discussion of the type series, including the holotype; followed by a statement of the general distribution of the taxon along with its state distribution, Next is a description of the taxon, followed by sections of similar species, systematics, habitat, behavior, reproduction, food habits, and remarks. The end of each species account contains a detailed dot map showing the distribution of each taxon for the state. The description of the taxon's state distribution is somewhat redundant. The distribution dot maps are self expanatory.

Towards the end of the book are sections presenting amphibians and reptiles of questionable occurrence in the state; list of scientific and common plant names used in the text; list of museum symbolic codes; a glossary; literature cited, and an index. The very last page contains a conversion table for Metric/English units of measure.

As with all new publications, there are a few glitches. Fortunately, the authors discovered most of these and sent (at least to some of us) a list of the errors. Those herpetologists familiar with the New Mexico herpetofauna were quick to recognize a few of the major errors. However, before we could alert the authors, they were already on top of these mistakes, and were rapidly advising the book owners of the errors (Price et al. 1996). I commend the authors for their rapid review of their own work. For the purposes of this review, I will rephrase the errors by category. Citations: errors on pp. 65, 114, 116, 308, 315, 380, 387, 409, and according to the authors, one citation is missing from p. 382 ([Cope, E.D. 1875; Bull. USNM (1):1–104]). One spelling error on p. 370; oviducal = oviductal; transcription errors: pl. 99, 100, pp. 253, 254. The authors note that they did not define the acronyms "GAB and GBPS" on p. 203, the figure in Fig. 18a is incorrect. The ventral surface of the tail should contain transverse black bars. The scale in figure 2 should read "900–2200", not "2000–12500" and the contour intervals are 100m, not 500m. The order of color rectangles are incorrect in Fig. 3. They should be blue-green yellow and brown. The animal pictured on plate 82 is from Socorro County, and the one pictured on plate 84 is from Eddy County.

It is difficult to evaluate how current a book is with respect to its information content without knowing the time-line the authors used for non-inclusion of the literature. In this case, 1994 appears to be the latest entry used in the literature cited section. The authors cite Wright's (1993) synopsis of *Cnemidophorus* systematics, but failed to follow his synonym list for the southwestern United States taxa of *Cnemidophorus* in their New Mexico herpetofauna checklist; e.g., placement of *C. t. reticulariens* (*sic*, Wright = *reticuloriens*) as a synonym of *C. t. marmoratus*. The discussion of its systematics wasn't necessary (pp. 228–229). The use of various generic names, e.g., *Spea* vs. *Scaphiopus*; *Trionyx* vs. *Apalone*; *Opheodrys* vs. *Liochlorophis*; *Elaphe* vs. *Senticolis*; *Elaphe* vs. *Bogertophis*; *Nerodia* vs. *Thamnophis* (for *rufipunctata*), are choices authors are forced to make based upon the most current knowledge available, but may not be the correct ones. Depending upon one's point of view, some readers will be happy with the choices of names, others will not, but that is the nature of the "beast."

This book is not a field guide. It is of large size, 8" x 10", and a reference guide for the amphibians and reptiles of the state of New Mexico. A field guide is surely contemplated by the University of New Mexico Press as a follow-up to this reference.

All in all, this is an excellent book. All students of herpetology should own a copy. This book will be the standard reference for the New Mexico herpetofauna for many years. At $35.00 a copy, almost anyone can afford to purchase a copy.

This guide to geckos and their care is a translation of the original German language edition published in 1991. It is divided into two primary sections, the first outlining the basic biology of geckos, their captive husbandry, and the materials and techniques of vivarium maintenance. The second section presents accounts of representative species divided by subfamily. Although some of the general biological information is out of date (e.g., the age and origin of geckos as a whole), most is accurate. The description of how gecko setae function, for example, is the only correct explanation I have ever seen in a popular work. Nonetheless, a few statements, such as those relating to the gliding ability of *Uroplatus* and the ability of *Teratoscincus* to breath through the skin, are not, as far as I know, supported by any published observations.

In Germany, vivarium keeping is both an art and a science. As might be expected, the sections dealing with captive care, behavior, and reproduction are especially authoritative. These are based largely, but by no means exclusively, on observations of *Phelsuma* spp. Details on vivarium construction and specifications are useful and the authors themselves are experts in this field. They present details for five general types of vivaria that, alone or in combination, will be appropriate for virtually all gecko species. Information is also provided about outdoor vivaria and free-ranging house geckos. There are short sections on raising feeder insects, breeding, and incubation. These are generally state-of-the-art. The section on diseases outlines common ailments, but the recent publication of a spate of reptile disease and parasite books renders the authors' citations outdated.

Although the book is not comprehensive, 43 genera and 76 species and subspecies are highlighted, as representatives of commonly kept (and some not so common) forms. Although most genera are represented by only one or two species, 13 forms of *Phelsuma* are detailed, reflecting the popularity of these colorful lizards in the pet trade. For each species highlighted the following categories are reviewed: distribution, habitat, size, characteristics, vivarium type, husbandry and reproduction, food, and similar species. Vivarium type and habitat are also summarized by genus in convenient tables for each subfamily.

There are several minor errors in this section. For example, *Lygodactylus picturatus* is ascribed to Peters 1896 (in fact the correct date is 1869), and the habitat description for *Pachydactylus oculatus* is not typical for that species. However, these issues do

not detract from the real value of the book: providing information pertinent to the keeping of geckos in the vivarium, with a primary concern for the captives' well-being.

The book is illustrated by 97 color photos and numerous line drawings. Although the photos are not outstanding, most are adequate portraits of terrarium specimens. Some could use cropping and one (on p. 149) appears to be printed upside down. If anything, the photos in the English version are somewhat clearer and brighter than in the German original. A corrected map, included as a separate insert in the original is incorporated in the translation, but with the original German labels.

The translation itself is generally accurate but in some places there are somewhat awkward literal translations of terms that have more appropriate English equivalents. Oddly, for a book published in the U.S., the translation is into British English. Metric measurements have not been converted and this may be problematic for many of the intended readers who will not be familiar with working in these units.

The literature cited section includes 148 entries. Apparently this section was not translated as terms such as "in Vorbereitung" (in preparation) are still present. Some errors in the original references have been carried over, such as Pregili for Pregill in the reference to Grismer (1988) and "C'ladistic" in Kluge (1987). New errors have been introduced, however, such as the all italics rendering of Bustard (1970), the missing "L" in Loveridge (1947), and the spelling *Stenodactylusz* in Remy and Remy (1990). Among other new errors, the genus *Eurydactylodes*, spelled correctly throughout in the German original, is uniformly misspelled as *Eurodactylodes* in the English version and Eocene is consistently misspelled as Eoscene. Most of the remaining spelling errors are minor and were carried over from the original German. These include some mistranslations in a table of Latin generic derivations, and some often misused specific epithets (e.g., *bibroni* instead of *bibronii*, *sauvagei* instead of *sauvagii*, *garnotti* instead of *garnotii*).

There are now many vivarium guides for lizards, and even a number directed specifically at geckos. One by Seufer (1991) also began life in Germany but was modified and expanded significantly before being published in the U.S. Although it covers much of the same ground as Henkel and Schmidt, only 29 taxa are highlighted, and there is uneven phylogenetic coverage, with only two species of diplodactylines covered. A recent book by Bartlett and Bartlett (1995) has an extensive section on U.S. native and introduced geckos and is geared more specifically towards an American audience. All of these books would be useful for the beginning gecko-keeper or enthusiast. However, Henkel and Schmidt's contribution is a must for anyone who is serious about keeping exotic geckos, including the more expensive and harder to obtain species. This book also does the best job of providing the nontechnical reader with an overview of the diversity among geckos. Although not cheap, this book would be a good investment for those who spend, or plan to spend, a large portion of their time and income on observing, breeding, and raising these fascinating lizards in captivity.

Chameleons are undeniably attractive animals, a fact that has not been lost on authors and publishers in recent years (e.g., Bartlett and Bartlett 1995; Le Berre 1995; Martin 1992; Schmidt et al. 1994). Petr Necas' contribution, *Chamäleons, Bunte Juwelen der Natur*, is the latest addition to the genre. Although it covers much of the same ground as its competitors, this book has some features to recommend it. Far more information is provided than in the competing works. In the general section on chameleon biology, especially detailed treatments are provided on topics such as the mechanism of tongue protrusion, hemipenial structure, and chameleons and human culture. Higher order systematics are reviewed and a list of recognized species is provided. The author follows the generic divisions of Klaver and Böhme (1986), recognizing six genera in the group.

Most of the remaining topics treated are related to husbandry and are similar to, though more detailed than, those in other chameleon books: behavior, reproduction, chameleons in captivity (an extensive section), terrarium set-up and requirements, and diseases. The second portion of the text presents accounts for 50 selected species. In comparison with other recent books, this provides the greatest breadth and balance of species coverage. Le Berre (1995) covers 30 species and the other authors fewer. Bartlett and Bartlett (1995) provide little information on species of *Brookesia, Rhampholeon* or *Bradypodion,* and Martin (1992) focuses on just four species in total.

Each species account provides Latin, German, and English names, a description (usually including a section on the significant sexual dimorphism characteristic of many species), "systematics and zoogeography" (essentially a review of any recognized subspecies and a statement of distribution), climate and biotope, biology and reproduction in captivity, and a numerically coded list of relevant literature. Although much information is presented, some of it is difficult to retrieve. Some text sections (e.g., that on terraria) are very long and do not have subheadings, and the presence of a detailed table of contents does not fully compensate for the lack of an index.

A short (eight page) glossary with more than 250 entries is included as an appendix and, in a significant departure from other books, 928 references are listed in the bibliography, facilitating further exploration of topics by the reader. Although not fully comprehensive, the bibliography has excellent coverage of works in English, German, French, Czech, and other languages and covers systematic and biological papers as well as those dealing with chameleons in captivity. This feature alone should make the book attractive to those with a serious interest in chameleons, even if they are unable to read the German text.

Illustrative material is variable in quality. The single computer-generated map is not well done and the line drawings are adequate at best. The 64 plates are grouped centrally, with 2–6 photos each. In total there are 250 color photos and five black and whites. The differing layouts of the plates break the monotony, but the wide borders around each photo result in a greater than necessary reduction of the smaller figures, and in some plates adjacent photo-

graphs are oriented at right angles to one another. Most photos feature head or body shots of chameleons, but others show x-rays, parasites, anatomical close-ups, terraria, eggs, postage stamps, *Dispholidus typus* (a chameleon predator), and a feeding sequence demonstrating the ballistic tongue of *Chamaeleo calyptratus*. The photo quality varies, but many do not have sufficient depth-of-field or are washed-out, and virtually all were taken in terraria with the back wall of the enclosure showing. In general, photo quality in competing books is superior. Bartlett and Bartlett (1995) provide mostly well-balanced and in-focus shots (along with a short section on photographing chameleons), Schmidt et al. (1994) present large, glossy photos of moderate quality, and Martin (1992) has some especially attractive close-ups.

Bunte Juwelen far exceeds its competition in price (all but Martin [1992] are relatively thin paperbacks selling for under $10.00). The fact that the book is written in German is an obvious drawback to most native English speakers. Nonetheless, it provides more information than the other titles combined, and its long list of references make it a generally valuable resource to those with a serious interest in chameleons. I recommend this publication to professional herpetologists on this account in particular. Its utility for amateurs and terrarium enthusiasts will depend largely on their facility in German and their level of sophistication. Those keeping only the more common and robust species may find the book overkill, but those who have or plan to obtain more specialized taxa may find the book of great use.

e-mail: rtremper@texas.net

The popularity of amphibian and reptile keeping has been increasing in a geometrical fashion for the last decade with no end in sight. With tremendous numbers of animals being kept as pets, research subjects, and commercial breeding stock has come an equally large number of medical issues.

Twenty years ago, medical treatment of reptiles was basically done by trial and error, with an emphasis on errors. The thought of applying veterinary medicine to a frog or salamander was unheard of. Then came the pioneering atlas by Dr. Fredric Frye and a generation of exotic pet keepers began to have hope after many a health crisis was successfully resolved. This tradition has been carried on by Dr. Mader and the thirty contributing authors who have made *Reptile Medicine and Surgery* a reality.

Dr. Mader knows that his field is vast and expanding daily, and therefore, was wise to enlist his colleagues' experience in compiling the seven sections of this work. Although Mader wrote the largest portion of this book he also was responsible for editing each contributed chapter. The latter was a chore that, he confides, was wrought with a personal struggle to let stand statements or opinions that were in conflict with his own views. As a reviewer and experienced keeper of herptiles, I am pleased that these controversial topics and opinions were published. For instance, among veterinarians there is one camp that uses classical therapy based on empirical scientific findings and another that considers the principles of metabolic scaling to be the preferred approach. Dr. Mader has delivered both points of view and it is left to the clinician to choose.

The introduction (Section I) contains a recipe that one could follow to develop a herpetology-based clientele, as well as lists of regional herp societies. The husbandry review and zoonoses chapters provide useful background information and form a firm basis for the following sections.

The biology of chelonians, snakes, lizards and crocodilians (Section II) is well presented and throughout the book the use of illustrations and photos help to engage the reader and further clarify the text. In fact, I am sure that this book will be utilized in a number of teaching situations because of the long list of subjects that are competently covered.

Section III, entitled Special Topics, deals with the major categories of animal physiology, such as the heart, eyes, nerves, skin, diseases, microbiology and parasitology, nutrition, reproduction, and abnormalities. As a test of the book's organization, I randomly chose the topic of hemipenis prolapse as a point of inquiry. After inspecting the index, I found that this subject is listed and covered in detail by multiple chapter authors. It was somewhat bothersome to flip between pages 223 and 395 to find all of the information on my subject and to deal with duplicated information written by two different authors. Although this form of duplication occurs several times among the various chapters, I would rather be faced with this type of fault than with a lack of information.

Sections IV and V, Special Techniques and Procedures, and Differential Diagnosis by Symptoms, respectively, are geared for the vet, vet technician, or even the advanced hobbyist who has experiences treating his or her own animals. I have personally dealt with thousands of reptile medical cases during my career and can therefore attest to the fact that the group of subjects presented by Mader and his colleagues is relevant and accurate.

I can't say enough about the high quality of the photographs that clearly illustrate the most common manifestations of the condition discussed and aid the reader in diagnosing problems. I could not find a single photo caption that is incorrect. In addition, the use of mostly black and white photographs has made the book affordable. With full color, which was not necessary for this publication, the price of the book would have been $150–175, out of the price range for many private individuals and beginning veterinarians.

I found Section VI, Specific Diseases and Conditions, to be the most useful for not only the medical community but also for the tens of thousands of private herpetoculturists, who inevitably will encounter a health emergency. These chapters are well-written and comprehensive. Dr. Mader hoped that this book would become a ready reference for any dilemma and it is these "meaty" chapters that assist in forming a diagnosis, establishing a treatment plan,

and delivering drug doses with ease and confidence, that realize this goal.

The final section (VII) of *Reptile Medicine and Surgery* presents overviews of some of the newest areas of herp medicine and research. Despite the book's title, amphibians are afforded some 23 pages of valuable information, and discussions of blood chemistry, artificial lighting, and sea turtle medical care are provided. The all-important drug tables, which many of us will consult frequently to determine the right amount of medicine to give to our ailing captives, also falls in this section.

Reptile Medicine and Surgery teaches, guides, reviews, and most importantly, resolves the medical issues presented by these animals. No volume of this type can ever be complete, but in the fine tradition of Dr. Frye, the work of Doug Mader and his colleagues will long stand as an important contribution to the field.

The Garter Snakes: Evolution and Ecology. By Douglas A. Rossman, Neil B. Ford and Richard A. Seigel. 1996. University of Oklahoma Press, Norman, Oklahoma. 332 pp. 15 color plates. Hardcover. US $69.95. ISBN 0-8061-2820-8.

LANI P. LYMAN-HENLEY

e-mail: lhenley@muw.edu

The authors of this book have set themselves a very tall order: an all-encompassing book on the genus *Thamnophis* written to appeal to professionals, students, and hobbyists. All of these audiences are certainly ripe for such a book, garter snakes being as ubiquitous as they are in both backyards and research laboratories. As a comprehensive overview of garter snake biology this book does an admirable job, especially in the face of the convoluted mess that garter snake taxonomy has been for so long. Unfortunately, few books aimed at such a diverse audience fully succeed, and I'm afraid that this book also falls short of its ambitious mission. Ironically, the problem primarily is in its very scholarly treatment of the aforementioned taxonomy of these snakes.

The book is organized in three sections: "Taxonomy and Evolution," "Ecology, Behavior and Captive Care," and "Species Accounts." Section I contains three chapters written by Rossman. Chapter 1, "Taxonomy and Relationships of Garter Snakes," is a thorough (but bland) discussion of the taxonomic history of the genus *Thamnophis*. This chapter also includes careful descriptions of morphological features of use in taxonomy that becomes a bit repetitive, especially regarding distinguishing between "superficially similar sympatric and parapatric species." Although this material is certainly important—we have been in dire need of an authoritative revision of the taxonomy of thamnophiine snakes for many years—I question it being the opening of the book. This is simply because it will be difficult reading for the less "taxonomically-sophisticated" (including the majority of the hobbyist audience) and may discourage such readers from continuing.

Chapter 2 is actually just tables of proposed garter snake names, in chronological order by their original name. It is an odd thing to have a chapter entirely sans narrative, and would seem to have been more appropriate as an appendix. Chapter 3 is a dichotomous key to the species and subspecies of *Thamnophis*. Again, somewhat odd content for a "chapter." The most glaring problem with this key is the gross error occurring at point 3 (the first option has no value listed). This is by far the most important typo among many still found throughout the book. My students tested the key using preserved specimens of several species of *Thamnophis* and found it difficult to use. The organization of the key includes some very precise features early on—e.g., numbers of maxillary teeth and ratios of facial scale measurements. It seems unlikely that anyone could be reasonably expected to follow this key without good calipers, a dissecting microscope, and preserved (occasionally skeletal) materials. Placing such fine details early on makes this especially problematic. It may have been more user-friendly to use the standard general-to-specific order for features where possible. We repeatedly found ourselves skipping ahead with known species and working backward through the key to follow the logic. All of these difficulties would be even worse with living specimens—let alone for users less familiar with keying out snakes. This seems to be the most salient example of the book serving its "technical" audience at the expense of other potential readers.

Section II includes chapters on ecology, behavior, and captive care, and is much more accessibly written for a "lay" audience. It begins with Chapter 4, "Ecology & Conservation of Garter Snakes: Masters of Plasticity", written by Seigel, in which garter snakes are roundly praised. It is pointed out that the majority of data on the genus is based on work involving a few species and populations, and that the review is therefore necessarily incomplete. Despite this caveat, it is a very thorough and comprehensive survey of the current state of information on the ecology of genus *Thamnophis*. Topics covered include Reproductive Ecology, Foraging Ecology, Population Ecology, Thermal Ecology, and Conservation.

Chapter 5 concerns the "Behavior of Garter Snakes." This chapter, written by Ford, opens with a nice treatise on the usefulness of Garter Snakes as Models for Studies of Behavior, followed by a section on Behavioral Capabilities focusing primarily on chemoreception. The sections on Foraging Behavior, Thermoregulatory Behavior, Antipredator Behavior, Orientation and Navigation, and Reproductive Behavior appear to be relatively comprehensive surveys. The sections on Habitat Selection, Hibernation, and Genetics & Evolution of Behavior are comparatively concise (but still good) reviews. The section on Learning indicates a special interest of the author, and is earmarked as an area in need of further attention. Given the quality and completeness of this chapter, it was quite a surprise to find the section on Aggregation to be lacking. The only type of aggregation mentioned is that of gravid females, despite the occurrence (and study of) several other manifestations of this phenomenon (e.g., Burghardt, 1983; Gillingham, 1987; Lyman-Henley & Burghardt, 1994—each of which also offers some review of the missing literature). This lacuna is especially disappointing given the opening lines of the chapter (quoted from Brattstrom, 1974) "Snakes may be the most asocial of reptiles (p. 90)." Studies into aggregation behavior are clearly the most direct window on snake sociality. Other than this oversight, the chapter is well written and concludes with a section on Future Studies, pointing out some lines of research that seem (to the author) in need of exploration.

Chapter 6 deals with Captive Maintenance of garter snakes. Also written by Ford, it is likely to be the most-read section of the book by hobbyists. It is on balance both well-done and thorough in scope, describing benefits and draw-backs to several different maintenance procedures. It is, however, certainly aimed at an audience assumed to be maintaining only a few snakes at a time, since some suggestions are rather time intensive—although it is noted that procedures for large lab populations are well documented for some species and suggested references are given. Personally, I found the short section on the treatment of snake mites surprisingly blase considering the devastation these organisms can wreak if infestations are allowed to become chronic. Oddly, the closing

section, The Future, doesn't really make any comments regarding the future.

The final section, III, consists of Species Accounts, jointly written. All species accepted by the authors (as detailed in Chapter 1) are covered in separate accounts that are in general quite good. Each account includes a unit on the taxonomy of the species, a range map, a unit on Life History and Ecology, and further units that vary somewhat depending on the information available for that species. All thirty species have a reference to at least one color plate, and a common name ascribed to them. For the most part, the species that are lacking in more detailed information are Mexican in origin. Of these, the only surprise is *T. melanogaster,* as there is now a rather extensive laboratory population maintained by several active researchers that seemingly would have allowed for more comments than are included here.

One assumes that for the most part some units are simply omitted given a lack of information. The account on *T. eques* specifically notes that "No literature on care of this species in captivity is available (p. 177)," and similar explicit comments in other accounts could have served as implicit research directions. Another point was the lack of any reference to the impact of the pet trade collection on populations of several species. It was noted that *T. radix* is a common pet store species, although my experience is that *T. sauritus, T. marcianus,* and brightly colored populations of *T. sirtalis* (e.g., the "Florida blue") are now regularly appearing on the reptile market. I have even occasionally seen specimens of *T. brachystoma, T. eques, T. cyrtopsis*, and *T. ordinoides* as well. Relatedly, one point in which I beg to differ is the opinion of the authors that *T. marcianus* is a particularly easy captive. Perhaps it is a population difference, but among my students, *T. marcianus* have been dreaded as charges due to their highly aggressive nature. Even *T. melanogaster* are preferred, being far less likely to actually bite.

The closing pages of the book contain a perfectly fine glossary, an index to scientific names, and the literature cited. There is no subject index, which could have been a useful inclusion for the student audience.

In all, Section I is written for professionals, and will likely be rather inaccessible to much of the potential audience of this book, as even the key requires materials beyond the scope of most people dealing with garter snakes. Sections II and III are written in a much more accessible style for a wider audience, and although it would be impossible to discuss every piece of research done on this wide-ranging and diverse genus, this book comes admirably close. Perhaps that captures my bottom line—"admirably close." It was with great enthusiasm that I accepted this review. As an active garter snake researcher for well over a decade now the very idea of this encyclopedic book was exciting to me. As such, perhaps I was overly disappointed by the various omissions (e.g., aggregation) of current literature. Despite its flawed key, occasional sins of omission, and uninviting price tag, I still highly recommend this book for coming so admirably close to the Herculean task of exhaustively documenting the genus *Thamnophis* for a broad audience.

V. WALLACH

Center for Vertebrate Studies, Biology Department
Northeastern University, Boston, Massachusetts 02138, USA
e-mail: vwallach@oeb.harvard.edu

This monograph treats eight New World and 32 Old World species of the genus *Elaphe sensu lato*. Written, illustrated, and photographed mainly by Schulz, there are four species accounts authored and one coauthored by A. Entzeroth. Illustrations were also provided by A. Gumprecht and T. Smith, with 1/4 the photographs contributed by more than 50 individuals. The book is beautifully executed on acid-free paper with a large type face. The first 75 pages deal with materials and methods, terminology, nomenclature, an expanded generic description, fossil records (with 80 references), geographic and elevational summaries, systematic species groups, distribution, natural history, reproduction, color variation, and husbandry. The species accounts cover 249 pages. A voluminous bibliography with 2810 references occupies 81 pages. Appendix I contains vernacular names of rat snakes in 40 languages. Appendix II lists the 613 preserved specimens examined from 16 institutions; 38 of the 40 species are mentioned (all but *rosaliae* and *vulpina*). The index is arranged by genus with species listed under the genera and subspecies listed under species, all in alphabetical order. As each binomial and trinomial combination is listed only once (under genus or species, respectively), it is inconvenient and time-consuming to find a name if only the original specific or subspecific epithet is known (as the species or subspecies names are not indexed). An index based on the species and subspecies names (with individual genera listed separately) would have been more useful as it is necessary to know all the generic synonyms of *Elaphe* (and their combinations) to locate a name in the index.

Each species account begins with scientific and vernacular names and contains a synonymy and sections on the type locality, holotype, description (color pattern), scutellation, distribution, natural history, husbandry and breeding, and literature. To economize space, references are numbered in the bibliography and listed only by number at the end of each account. When subspecies are recognized, the preliminary portion of the account contains all of the above sections except synonymy, type locality, and holotype; each subspecies account then follows with sections on synonymy, type locality, holotype, description, and distribution. Species accounts are 2–14 pages in length, with most species treated in 3–7 pages. Each account has a beautifully illustrated dorsal and lateral head view plus at least one dot range map. There are supplemental illustrations of head, head and anterior body, midbody pattern, or ventral pattern in 27 accounts. Each account concludes with a synopsis of the husbandry conditions necessary to maintain the species in captivity and available data on breeding behavior and habits.

The color plates are generally superb and contain 420 photos (usually arranged 8 on a plate). Thirty-seven of the 40 species are illustrated from life (*cantoris*, *leonardi*, and *perlacea* from paintings and preserved specimens only). In addition, there are 14 habitat photos, 24 of preserved specimens, and 27 of miscellaneous subjects. The photography is excellent and only about ten of the photos (from contributors) are not perfectly focused or are poorly composed.

The distribution maps are clear, legible, full-page dot maps (only a few well-known species have solidly shaded ranges as in field guides). National boundaries are outlined (sometimes even provinces or states), countries are labelled, type localities are indicated, and large cities and major rivers are also included. Multiple species or subspecies on a single map are depicted using different symbols. The first nine summary tables are most informative and useful, including data for each species on scale counts, dentition, elevation, distribution by country, prey preferences, and reproduction.

The typescript and proofreading are impeccable. I found only two misspelled words (p. 84: presubcocular; p. 215: seperated), two misspelled surnames (p. 27: Bachmeyer; p. 190: Lanzell), two misspelled place names (p. 284: Upsala; p. 297: Isla), and two misprinted years (1064, p. 111; 1833, legend pl. 1). Considering that the English version is a translation from the original German, the syntax and grammar are excellent. The main grammatical complaint is with the incorrect placement of commas (or absence of them when needed), and this error must be attrributable to the South African group that performed the translation (Herprint International). When referring to body coloration, "in" is consistently substituted for "on," there is frequent use of the adjectival form of a color (grayish, yellowish, greenish) in place of a noun, and occasionally an "s" is omitted on plural words or added on a singular noun. Temperment is often referred to with the terms "shy" or "shyness" when a reclusive or secretive nature is implied and "vicious" when irritable is more appropriate. The consistent capitalization of vernacular snake names and/or their consolidation into one word (as Ratsnake) is a minor irritation. The minor criticisms above are probably attributable to the original language of the book being German.

The major failing of this work is in the area of nomenclature and systematics. It is acknowledged that the author is an amateur and while he has undoubtedly compiled the most detailed, comprehensive, and profusely illustrated treatise ever on rat snakes, it is surprising that the scientific consultants (W. Böhme, N. Helfenberger, and M. Ruf) did not more carefully review the systematic sections. Presentation of the type concept and its ramifications is poor and definitions of holotype, syntype, paratype, lectotype, neotype, and *nomen substitutum* are inaccurate and misleading. The designation of a holotype (or any type for that matter) was not practiced until about 50 years ago. If no type has been designated (as in the older literature), all specimens upon which the description is based are syntypes and none may ever become a holotype, although a lectotype can be selected from the original syntypic series and holds the same status as the holotype. Also, a number of type locality restrictions are incorrectly cited or misconstrued, and sometimes a syntype or lectotype is referred to as the holotype. It was a common practice in earlier times to exchange one of a series of syntypes with other museums and the BMNH and MCZ did so for many specimens.

The standardized employment of a single "i" termination for patronyms, in my opinion, contravenes the spirit of the Code and original intent of the author. When the original orthography includes a "ii" ending, it should be preserved as such, and vice versa. This is unambiguously stated in the Code: Articles 31(a), 31(a)(iii), 32(b), 33(d), and 34(b). Thus, three species of rat snakes (*hodgsonii*, *jansenii*, and *schrenckii*) should have the "ii" endings.

In my opinion the most substantive error is the decision to regress a century in taxonomic enlightenment back to a Boulengerian concept by synonymizing the genera *Bogertophis*, *Gonyosoma*, and *Senticolis* with *Elaphe*. Not only is *Gonyosoma* a valid genus as diagnosed by Dowling (1958), but it also differs from *Elaphe sensu stricto* in having a chambered avascular tracheal lung. Besides *G. oxycephalum*, this lung structure is present in at least *G. cantoris* and *G. hodgsonii*. I am in agreement with the author that a genus should not be split until a comprehensive study has been accomplished. However, in the case of the New World rat snakes, it is just a matter of time before they are separated (as they represent a monophyletic clade) under the name *Pantherophis*, and I believe that both *Bogertophis* and *Senticolis* are justifiably distinct. *Bogertophis* possesses two derived features that separate it from all other New World species: absence of the left lung complex and a $2n = 40$ karyotype. All four genera could have been recognized and the title of the book changed to "*Elaphe* and kin" or "*Elaphe* and related rat snakes" without compromising the integrity of the work. This surely would have been an asset rather than a liability. The nomenclature in an important work such as this, which will be the standard for rat snakes for many years to come, will be followed blindly by those who are not specialists in colubrine systematics or who are ignorant of classification in general, resulting in confusion in the literature and hinderance of our understanding of colubrine systematic relationships. Ironically, Schätti's separation of *Hierophis* from *Coluber* is recognized even though a thorough revision of *Coluber* has yet to be completed.

Treatment of subspecies is based upon solid data or consensus of opinion, and with controversial names the author professionally discusses his reasons for the recognition or synonymy of taxa. Questionable systematic procedure involves relegating *Coluber enganensis* Vinciguerra to a subspecies of *E. subradiata*, and considering *E. laeta intermontanus* Woodbury and Woodbury (1942) as a more distinctive form of *E guttata* than *E. g. meahllmorum* Smith et al. (1994). Omissions include the genus *Tyria* Cope (1862), a substitute name for *Zamenis* Wagler, and one fossil species, *Elaphe longivertebrata* Szyndlar (1984). Also, *Elaphis rhombifer* Jan, 1863 is omitted from the synonymy of *E. moellendorffi*. Erroneous subsequent spellings (or typos) of *Elaphe* that were overlooked in the list of misspellings include *Elapho* Bleakney (1958), *Elaphus* Shrestha (1981), *Elahe* Mahendra (1984), and *Elapne* Murthy (1986).

The type locality star is omitted from Map 44 for the type of *E. o. spiloides*, perhaps intentionally because of the apparent taxonomic problem involved. However, designation of "La Nouvelle-Orleans" as the provenance in 1854 probably meant "within the vicinity of New Orleans," and neighboring Mississippi is well within the vicinity. Stanford University is not in San Francisco or related to the California Academy of Sciences, but former SU specimens are now in CAS (CAS-SU). The type of *Elaphe philippina* Griffin is in CAS. *Elaphis q. atra* and *E. q. interrupta* are dated Jan, 1867. Whereas *Coluber quater-radiatus* Gmelin is correctly allocated to the synonymy of *E. quatuorlineata*, *Coluber elaphis* Shaw antedates *E. scalaris* Schinz; since the *nomen oblitum* rule is no longer in effect, suppression of Shaw's name is necessary. The original illustration of *Coluber quatuorlineatus* Lacépède is on pl. 7.

A few errors are attributable to carelessness: the collector of the type of *B. rosaliae* is L. Diguet; the type locality of *E. enganensis* is Boea-Boea and Malakoni; *Coluber alleghaniensis* and *C. quadrivittatus* Holbrook were described in 1836; the description of *Elaphis* Bonaparte is dated 1834; *Callopeltis* was described by Fitzinger *in* Bonaparte (1834 *in* 1832–1841) and *Simus* was described by Fitzinger *in* Bonaparte (1838 *in* 1832–1841); *Compsosoma* and *Plagiodon* were described by Duméril (1853); the type of *Elaphe moellendorffi* is SMF 18476 (8056, 1a is the old Boettger no.). ZIL 3706 is the lectotype of *E. schrenckii*, as designated by Stejneger (1907). The type of *E. situla* is deposited in Stockholm (NHRM).

It is a pity that no identification key is included in this monumental work. With the details of scutellation, color patterns, and distribution presented by Schulz, it would not be very difficult to construct a workable key. For instance, an American key, an Indonesian key, and an Asian (perhaps southern and eastern) key could be compiled. In fact, Staszko and Walls (1994) constructed workable keys to the American and European species. Another omission is neglecting to mention dicephalic ratsnakes. Although the author discusses in detail various color anomalies (melanism, albinism, leucicism) of *Elaphe* and cases of twin specimens hatching from single eggs, he fails to mention that two-headed specimens are known in ten species (*climacophora*, *dione*, *guttata*, *longissima*, *obsoleta*, *quadrivirgata*, *quatuorlineata*, *rufodorsata*, *schrencki*, and *vulpina*). There are at least 30 references to dicephalic *Elaphe* (from 1926–1995), of which only five are listed in the bibliography.

The extensive bibliography is impressive and remarkable for its completeness of coverage of both the professional scientific literature and the amatuer husbandry and herp journals. Although I do not have access to many of the journals cited (*Bl. Aquar-Terrar., Elaphe, Herpetofauna, Herptile, Sauria, Snake Keeper*), in which mostly husbandry articles are present, I can comment on the high quality of the other works included. The coverage of taxonomic, systematic, ecological, and distributional publications is thorough and comprehensive. However, a casual search of my library revealed more than 50 omitted *Elaphe* references, dating from 1861–1995. Most surprising is the omission of the rat snake book by Staszko and Walls (1994), which was previously the most complete work on the group (including all species recognized by Schulz except *persica*).

My main criticism of the bibliography is inattention to details, especially of actual dates of publication (rather than title page dates), but also to author's initials, series and volume numbers, and publishers. From scanning the literature available to me, the errors are certainly minimal and some examples follow, the most critical relating to publication dates. The following numbered citations are correctly dated as follows: #101 (1968), #238 (1900), #329 (1902), #692 (1974), #1003 (1891), #1336 (1979), #1351 (1890), #1371 (1939), #1386 (1894), #1469 (1876), #1672 (1880), #1677 (1893), #1749 (1912), #1747 (1905), #1797 (1910), #2198 (1932), #2652 (1989), and #2764 (1994). Corrected series (s.), volume (v.), and numbers (n.) are as follows: #101 (v. 1966–67), #329 (v. 54), #1206 (v. 11), #1277 (n. 3), #1627 (s. 3, v. 2), #1630 (v. 11, n. 2), #1631 (s. 9, v. 7, n. 5), #1683 (v. 31, n. 25), #2046 (s. 7, v. 8), #2045 (s. 7, v. 1), and #2499 (v. 60). Corrected names and initials of authors include: #261 (E. G. Boulenger), #792 (W. Freedman), #1077–78 (R. Honegger), #1085 (B.-Q. Hu, M.-H. Huang, Z.-T. Xie, E.-M. Zhao, Y.-M. Jiang, Q.-Y. Huang, Y. Zong, and J.-F. Ma), #1170 (J. de Jongh), and #2172 (C. E. Shaw). Corrected publishers include: #1317 (SSAR), #2052 (Amphibia-Reptilia), and #2152 (Unpubl. Ph.D., Univ. So. California). A typo on #1134 is pp. 382–383. One author is cited under two surname variants, #407–408 (Carevskij) and #552 (Czarewsky), #943 is not a 2nd ed, merely a reprint, and #1757 is published by Ernest Bourdin and has 756 pp. The citation for Massalongo (1854) is omitted.

Notwithstanding all the nit-picking criticisms, I am duly impressed with the quality and thoroughness of this book. While the errors mentioned above may seem substantial, in reality they are miniscule compared to the massive volume of summarized information. An excellent resource for both the professional herpetologist and the amateur hobbyist, it is the *opus magnus* of rat snakes. This monograph belongs to the class of the best herpetological books, such as Campbell and Lamar's "Venomous Reptiles of Latin America" (1989), Ernst and Barbour's "Snakes of Eastern North America" (1989), Gloyd and Conant's "Snakes of the *Agkistrodon* Complex" (1990), Mitchell's "Reptiles of Virginia" (1994), and Palmer and Braswell's "Reptiles of North Carolina" (1995). It contains essentially the sum of our knowledge of these snakes, taken from the international academic and hobbyist literature, and including the author's unpublished records. Presented in an understandable and enjoyable reading style, it lacks the dryness of most technical writing. This book is clearly a labor of love; words cannot adequately describe the meticulous and superb effort that went into producing this beautiful and informative work. While it will not be (and is not intended to be) the last word on *Elaphe* and kin, it will remain the standard classical reference on the group, and hopefully will stimulate further research and collection of the poorly known species. As an indispensible guide to the world's rat snakes, no herpetological library will be complete without it. Although it is not inexpensive, the quality of the artwork and information content justify its high price. Unfortunately, due partly to inflation and the cost of color reproduction, superior monographic treatments today cost $100 or more.

PUBLICATIONS RECEIVED

Venomous and Poisonous Marine Animals: A Medical and Biological Handbook, edited by John A. Williamson, Peter J. Fenner, Joseph W. Burnett, and Jacquie F. Rifkin. University of New South Wales Press, Sydney. 1996. Hardcover. 504 pp. + 80 pages of color plates, US $130.00 (available from International Specialized Book Services, Inc., 5804 N.E. Hassalo Street, Portland, Oregon 97213-3644, USA). ISBN 0 86840 279 6.

This large book provides an extensive overview of venomous marine organisms and their toxins as well as the human injuries (and associated treatments) produced by contact, injection, or ingestion of these toxins. Although the emphasis is on Australian marine organisms, the coverage is worldwide in scope. The herpetological content is restricted to sea snakes and *Crocodylus porosus*. The latter is illustrated by a single photograph and mentioned in comparison of Australian shark and crocodile attacks/fatalities. Sea snakes are treated in a short (seven page) chapter and in passages in sections dealing with marine antivenoms, and venomous and poisonous marine animals of the Gulf of Oman and Japan. Nine photos in the color plate section are devoted to sea snakes, with bite victims' wounds figuring prominently.

1996 Herpetological Index, compiled by Breck Bartholomew. Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA. 1997. Softcover. 151 pp., US $20.00 (also available

on disk as a text file or EndNote database file for Macintosh or PC for $15.00 each).

This fourth annual compilation includes complete citations for 3743 herpetological publications taken from a wide variety of sources, including national, international, and regional herpetological journals and newsletters as well as herpetocultural magazines. The citations are indexed by author and subject (including taxonomic, geographic, and topical listings). Although most of the publications cited were published in 1996, older references that have been newly added to the compiler's database are also listed. Although the bibliography is not complete (herpetological citations from many general zoological journals are lacking, for example), it is an economical alternative to *Zoological Record*, the 1995/96 amphibian and reptile volumes of which referenced 4935 publications at a subscription cost of more than US $300.

Schildkröten — Krokodile — Brückenechsen [Turtles — Crocodilians — Tuataras], by Heinz Wermuth and Robert Mertens. Gustav Fischer Verlag, Villengang 2, D-07745 Jena, Germany. 1996. Hardcover. xxvii + 506 pp. ISBN 3-437-35048-X. DM 178.—(approx. US $120.00).

A reprint of the classic 1961 systematic review of the living non-squamate reptiles. The body of the book includes keys, complete synonymies, statements of distribution, and black and white illustrations (many taken from the original descriptions) of all of the turtles, crocodilians, and tuataras then recognized. All Latin names are fully indexed. The reprint itself is accompanied by a short postscript by Wermuth and by a more extensive commentary (with dual German-English text) by Fritz Jürgen Obst. The commentary incorporates a chronological list of the 117 turtles and four crocodilians described since 1961, a summary of major changes in the systematics of turtles, crocodilians, and tuataras, and extensive tables listing the names employed by Wermuth and Mertens and nine subsequent checklists and reviews. The tables serve as guide to the changes in turtle and crocodilian taxonomy over the last 35 years.

Handbook of Ethological Methods, Second Edition, by Philip N. Lehner. Cambridge University Press, 40 West 20th Street, New York, New York 10011-4211, USA. 1996. Hardcover. xix + 672 pp. ISBN 0-521-55405-5. US $ 69.95.

An expanded and updated version of the 1979 edition of this standard reference. The book begins with a conceptual model of animal behavior and includes major sections dealing with research design, data collection (methods and equipment), and data analysis. The section on statistical methods, in particular, has been expanded relative to the first edition and the data collection equipment chapter has been updated to reflect current technologies. The *Handbook* concludes with appendices on microcomputers in ethology, ethics in ethology, and guidelines for the use of animals in research. There is a 1000-entry reference list and the work is subject-indexed. Although a limited subset of the examples provided in the *Handbook* are herpetological, many of the methods are generally applicable to any group of study organisms.

Listado Preliminar de la Fauna Silvestre del Estado de Nuevo León, México, by Salvador Contreras-B., Fernando Gonzales-S., David Lazcano-V., and Alberto Contreras-A, editors. 1995. Consejo Consultivo Estatal para las Preservación y Fomento de la Flora y Fauna Silvestre de Nuevo León. Gobierno del Estado de Nuevo León, México. 152 pp., softcover. Price not given. ISBN 968-7644-001. Monterrey, Nuevo León.

This small book is, as the title suggests, a preliminary checklist of the mammals, birds, reptiles, amphibians, fishes, insects, arachnids, crustaceans, and mollusks of a remarkably diverse region of northeastern México. Although consisting largely of species lists, descriptive summaries of each faunal group are presented in both Spanish and English. Arturo Contreras and David Lazcano prepared the herp checklists (two chapters), and these occupy about 14 pages. Common names (in Spanish) accompany the scientific names for each species.

ERRATUM

In the paper by Hollingsworth et al. (1997. 28:26–28), we inadvertently omitted Table 1, shown below.

TABLE 1. Variation in eight meristic characters for *Sauromalus varius* from islas Roca Lobos and San Esteban. Upper figures = limits. Middle figure = mean. Lower figure = ± one standard deviation. n = sample size. See text for character acronyms and definitions and for a discussion on the male-female separation of dorsals.

Population	VENTRL	CAUDAL	BRACHL	DORSAL (Male)	DORSAL (Female)	FEMPOR	SUPRAL	INFRAL	ROSTRL
Isla	147–160	32–39	50–57	36–40	32–34	31–36	27–33	30–35	4–5

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). E-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1997 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July (Theodore Pietsch, Chair).
1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).

Society for the Study of Amphibians and Reptiles
1997 Annual Meeting
together with
American Society of Ichthyologists and Herpetologists
and
The Herpetologists' League
26 June – 2 July 1997
University of Washington, Seattle, USA

Keynote Address: "Frogs, Unpredictability, Flexibility, and the Future," by Martha Crump (Northern Arizona University).

Symposium: "Nuclear DNA and the Evolutionary Genetics of Fishes, Amphibians and Reptiles." *Organizer*: Andrew M. Shedlock, University of Washington, FTR, Box 355100, Seattle, Washington 98195, USA; e-mail: shedlock@u.washington.edu.

Symposium: "Ecological Processes: Insights from Field Experiments and Natural History." This symposium celebrates the career and contributions of Margaret McBride Stewart in honor of her 70th birthday. *Organizer:* Kiisa C. Nishikawa, Department of Biological Sciences, Northern Arizona University, Flagstaff, Arizona 86011-5640, USA; e-mail: Kiisa.Nishikawa@nau.edu.

Symposium: "Comparisons and Current Uses of Phylogenetic Approaches to Ichthyology and Herpetology." *Organizer*: Mark Pyron, Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA; e-mail: Pyron@uiuc.edu.

Symposium: "Chemical Ecology of Predator/Prey Relationships Among Fishes, Amphibians, and Reptiles." *Organizer*: Alicia Mathis, Department of Biology, Southwest Missouri State University, Springfield, Missouri 65804-0095, USA; e-mail: sam477f@vma.smsu.edu.

Symposium: "Life History and Ecology of Chelonians." *Organizer*: R. Bruce Bury, National Biological Service, 3080 SE Clearwater Driver, Corvallis, Oregon 97333, USA; e-mail: buryb@mail.cor.epa.gov.

Symposium: "Biosystematics, Behavioral Ecology, and Conservation of Iguanas." *Organizer:* William K. Hayes, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA; e-mail: whayes@ccmail.llu.edu.

Conservation Forum: Point-Counterpoint. "Sustainable Use of Amphibian and Reptile Resources." *Organizer:* C. Kenneth Dodd, Jr., SSAR Conservation Committee, 5222 NW 56th Court, Gainesville, Florida 32653, USA; e-mail: kdodd@nervm.nerc.ufl.edu.

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day in or near the University of Washington's Husky Union Building. Poster sessions will be held at the HUB.

Student Paper Awards: Seibert Prizes will be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize).

Multimedia Presentations: "Herps of the West" and "Amphibians of the Appalachians" by David Dennis and Eric Juterbock; "Herpetological Namesakes" by Kraig Adler and David Dennis.

Social Activities: General Reception at Seattle Aquarium, Auction, Salmon Barbecue, Graduate Student Reception, Banquet.

Live Exhibit: Live herps of the Pacific Northwest, sponsored by the Society for Northwestern Vertebrate Biology and the Pacific Northwest Amphibian and Reptile Consortium. As usual, a diverse array of animals will be available for viewing and photography.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Field Trips: Mount Saint Helens National Volcanic Monument and Snoqualmie Pass–Ellensburg.

Costs: Pre-registration US $120 regular, $60 student, $60 accompanying person. After March 15, costs are $145 regular, $75 student, and $75 accompanying person.

Further Details: Contact T. W. Pietsch, School of Fisheries, University of Washington, Box 355100, Seattle, Washington 98195-5100, USA. Tel. (206) 543-8923; e-mail: twp@fish.washington.edu. Meeting Announcement and Call for Papers were mailed to all U.S., Mexican, and Canadian members of SSAR in late November 1996. Other persons wishing to receive this information may do so by contacting Ted Pietsch at the address above. A World Wide Web page devoted to meeting information may be found at: http://artedi.fish.washington.edu/asih/asih97.html.

SSAR BUSINESS

SSAR Grants-in-Herpetology Committee Annual Report (1997)

Six awards of $500 each were made this year, as follows:

Conservation.—**Jennifer L. Mook**, Clemson University. Project title: "Determining paternity and genetic diversity of radiated tortoises (*Geochelone radiata*): utilizing randomly amplified polymorphic DNAs in the zoo."

Laboratory Research.—**Sharon Downes**, University of Sydney. Project title: "Effects of incubation environment on the vulnerability of scincid lizards to predation by snakes: a test of foraging theory and the ecological significance of phenotypic plasticity."

Field Research.—**Louise M. Armstrong**, University of Massachusetts. Project title: "Patterns and processes of speciation in desmognathine salamanders."

Travel.—**Maureen Kearney**, George Washington University. Project title: "Evolution of the Order Amphisbaenia based on evidence from fossil and recent forms."

Education.—**Matthew R. Chapman** and **Peter K. Ducey**, SUNY, Cortland. Project title: "Distribution and conservation of amphibians and reptiles in New York."

International.—**Sergius L. Kuzmin**, Russian Academy of Sciences. Project title: "Eastern range margin of the Semirechensk salamander (*Ranodon sibiricus*)."

1997 Grants-In-Herpetology Committee.—Dr. Carole L. Hom, University of California, Davis; Dr. Julian C. Lee, University of Miami (chair); Joseph Mendelson, III, University of Kansas; Janice Perry, Arizona-Sonora Desert Museum; Dr. Barbara Savitzky, Christopher Newport University; Dr. Kelly Zamudio, University of California, Berkeley.

NEWSNOTES

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due by 15 October 1997, with notification by 1 December 1997. Grantees are expected to complete their Academy visit by 15 September 1998. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

About Our Cover

There are nine species of snakes in the genus *Leptophis*, and they range, collectively, from México south to central Argentina. Nearly all are arboreal and diurnal, hunting for frogs, which constitute their primary prey. Parrot snakes, as they are called, are not considered venomous in the traditional sense, although their bite is known to cause symptoms of envenomation in humans (Minton 1978. Nat. Hist. 9:56–60).

During the 1940's, James A. Oliver published a series of papers and a generic revision of *Leptophis* (1948. Bull. Amer. Mus. Nat. Hist. 92:157–280), and his arrangement generally has been followed since. In fact, the only systematic novelties involving *Leptophis* subsequent to Oliver's monograph are the resurrection of *L. cupreus* (Peters and Orcés-V. 1960. Beitr. Neotrop. Fauna 2:139–141), the revalidation of *L. modestus* (Hoyt 1964. Copeia 1964:214–215; Mertens 1973. Stud. Neotrop. Fauna 8:141–154), and the description of *L. stimsoni* (Harding 1995. Trop. Zool. 8:221–226).

Brightly colored, alert, and graceful, parrot snakes are well known to people in rural Latin America. Frequently, their green coloration and tendency to gape defensively earn them a death sentence. This is unfortunate because parrot snakes are inoffensive creatures, often unwilling to bite when provoked. The snake depicted on the cover is *Leptophis ahaetulla*, with eleven races ranging from México to Argentina.

America lost one of its most outstanding herpetological artists on October 6, 1996, with the death of **Philip E. Sims**. His unique style—focusing on the symmetry and patterns of reptilian scales, skin, and especially eyes—immediately is recognizable and had won him widespread recognition among artists and herpetologists alike. His work hangs in several public galleries and he was awarded numerous prizes for his work. Phil grew up in Colorado, where he learned to appreciate reptiles under the guidance of his father, a high school biology teacher. He earned his bachelor's and veterinary medicine degrees at Colorado State University and later went on for a Master of Science degree in biomedical illustration. He generally painted in watercolors applied with airbrushes. The iridescent scales are created by applying acrylic paint and the edges are sharpened using colored pencils. The overall result is a stunning image, at once accurate natural history and fine art. Phil most often depicted snakes, which he felt were so unappreciated, despite his encounter with a 20-foot long reticulated python, an erstwhile patient, that had swallowed his arm up to the shoulder! His art studio was shared with many terraria filled with lizards and snakes. Although he was a practicing veterinarian, natural history art was increasingly occupying his time—at the time of his death he was spending three weeks out of four doing art—and his goal was to become a full-time artist. He had nearly completed a book, "Atlas of Comparative Reptile Anatomy," and planned to issue limited-edition prints of his artwork, in order to promote the conservation of these creatures he so deeply respected and enjoyed. Through the courtesy of his father, SSAR is honored to reproduce this drawing as a tribute to the memory of Phil Sims.

Separation and imaging of Sims's artwork is by **Jim Bridges** of Herpeto Inc., Hollywood, Florida, USA.

African Herpetofaunal Biodiversity Programme (AHBP)

The interim committee of the AHBP invites you to participate in an e-mail discussion (on the Afriherp-L list) of the mission, aims, and objectives of the AHBP. We also will discuss the possibilty of a workshop and election of a new committee to be held at the 3rd World Congress of Herpetology in Prague in August. This invitation is particularly directed toward everyone interested in the herpetofauna of Africa and its islands (including the Malagasy region).

For those of you who are not already subscribers to Afriherp-L, you can subscribe by sending a message to listproc@wcmc.org.uk with only the text "subscribe afriherp-l (your name)" in the body of the message. Remember to leave the subject line blank and to switch off your signature. To receive a copy of your own postings, set mail to "ack." You can also subscribe in digest form.

The AHBP Interim Committee consists of Michael Lambert (Chairman), Ivan Ineich (Deputy Chairman), Lynn Raw (General Secretary), Neil Burgess (Mapping Coordinator), Preston Hardison (Data Management Coordinator), and Craig Hassapakis and Martin Kundrat (Publicity and Public Relations Coordinators). For additional information contact: *Lynn Raw (using gdr@iafrica.com) P.O. Box 200 (also on raw@zoology.unp.ac.za) Merrivale 3291, South Africa. Tel. +27-331-431360.*

Carettochelys Studbook Information Needed

Information is needed for inclusion in a new American Zoo Association-approved studbook for the North American Region on currently living or historically held pig-nosed turtles, *Carettochelys insculpta*, also known as pitted shell turtles, Fly River turtles, or New Guinea plateless turtles. If you or your institution currently or historically held individuals of this species or received/used tissue, blood, or other samples, I would like to hear from you. Turtles that never reproduced or were turned over to a museum collection are valuable inclusions to studbooks. Likewise, if your institution would be interested in receiving a deceased pig-nosed turtle or a living specimen, I will include your interest in the studbook. All participants will receive a copy of the studbook when completed. Contact: *William H. Espenshade III, The Zoological Society of Philadelphia, 3400 West Girard Avenue, Philadelphia, Pennsylvania 19104-1196, USA. Tel. (215) 243-1100 ext. 3262; Fax (215) 243-5385; e-mail: WHE3@aol.com.*

NSF Grant for SIUC Collection

The 300,000-specimen Zoology collection at Southern Illinois University at Carbondale has received a two-year grant from the National Science Foundation to sustain the largest collection of fishes, amphibians, and reptiles in Illinois, Indiana, Missouri, and Kentucky. Ron Brandon (herpetologist) and Brooks Burr (ichthyologist) individually have managed the collections of herps and fishes until now. The grant will permit the hiring of a full-time collections manager. The collection is housed in a newly-opened 3500-square-foot Fluid Vertebrate Collection Center in SIUC's year-old Life Science III Building. For collection information contact: *Ronald A. Brandon, Departement of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA; e-mail: Brandon@Zoology.siu.edu.*

Herpetologist, The University of Kansas

The Natural History Museum and Department of Systematics & Ecology, The University of Kansas, invite applications for an open-rank position as a faculty-curator in herpetology. Successful applicant will serve as a museum curator in the Division of Herpetology and as a faculty member in the Department, will be able to teach reptile biology and other courses, direct undergraduate and graduate research, and have an active, specimen-based research program with potential for extramural funding. Preference will be given to individuals who specialize in reptile biology, conduct herpetological field studies, have a strong commitment to research and education at undergraduate and graduate levels, and show commitment to service to the discipline, and evidence of administrative skills and ability to interact with the public. Submit curriculum vitae; statements of (1) teaching philosophy, experience, and interests, including preferred courses to teach, (2) research interests, goals, and current research activities, and (3) curatorial philosophy and experience, including perceptions of the roles of systematic collections and museums in biological pursuits; 2 copies of selected publications or manuscripts; and names, addresses, voice and FAX numbers, and e-mail addresses of 3 persons to be contacted as references. Forward materials to Dr. Linda Trueb, Chair, Search Committee, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA. Review of applications will begin 01 September 1997 and continue until the position is filled. Position availability is contingent on budgetary approval. EO/AA Employer.

New Journal Announced

The IUCN/SSC/DAPTF/Regional Group for the Commonwealth of Independent States and the Institute of Ecology and Evolution of the Russian Academy of Sciences have launched a new journal, *Advances in Amphibian Research in the Former Soviet Union*. The journal will publish papers (in English) on all aspects of amphibian research by authors from the former Soviet Union as well as papers by foreign authors that concern amphibians within this territory. All topics of batrachology are desired, including systematics, distribution (including new records, maps, and atlases), ecology, behavior, conservation, morphology, evolution, paleontology, physiology, biochemistry, parasitology, genetics, and herpetoculture. For manuscript format requirements, subscriptions, or other information, contact: *Dr. Sergius L. Kuzmin, Editor, Institute of Ecology and Evolution, Russian Academy of Sciences, Leninsky Prospect, 33, Moscos 117071, Russia. Tel. (7095) 954-32-62; Fax (7095) 954-55-34; e-mail: sevin@glas.apc.org.*

Gopher Tortoise Council Awards

The Gopher Tortoise Council annually presents the J. Larry Landers Student Research Award to the best student research project concerning the biology of the gopher tortoise, *Gopherus polyphemus*, or any aspects of its sandhill community. Last year two awards were presented to Melissa Dills of Auburn University ("Coloniality in the gopher tortoise, *Gopherus polyphemus*") and Karl Studenroth ("A survey of the occurrence of *Gopherus polyphemus* on the campus of the University of Mobile"). Recent awards

have averaged $500. Students interested in applying should submit a concise description of their project with a detailed budget and a brief curriculum vitae to: *Bob Herrington, Research Advisory Committee, Department of Biology, Georgia Southwestern State University, Americus, Georgia 31709, USA.* Deadline for receipt of proposals to be considered for the 1997 award is 31 August 1997.

Iguanas of the West Indies Poster

The Fort Worth Zoo announces the publication of a beautiful new poster highlighting the conservation of iguanas of the West Indies. Featuring rare and exceptional color photographs of 14 of the 18 *Cyclura* and *Iguana*, this high-quality poster measures 20 x 26 in. and is printed on a heavy-duty paper stock suitable for framing. Produced to assist the IUCN/SSC West Indian Iguana Specialist Group in promoting the preservation of these endangered lizards, all proceeds from the sale of this poster will help to fund critical iguana research and conservation projects throughout the Caribbean. Posters can be obtained in the U.S. for $13.00 including postage and mailing tube; international orders are $16.00. Checks or money orders (in U.S. currency) should be payable to the Fort Worth Zoo. Mail requests to: *Rick Hudson, Fort Worth Zoo, 1989 Colonial Parkway, Fort Worth, Texas 76110, USA.*

REGIONAL HERPETOLOGICAL SOCIETIES

Slovenian Herpetological Society Formed

The Drustvo za gojenje in proucevanje plazilcev in dvozivk [Society for Breeding and Research of Reptiles and Amphibians] was founded on 7 September 1995 in Ljubljana, Slovenia. It is the first society of its kind in Slovenia. The Slovenian herpetofauna is very diverse for such a small area, but is still poorly known and needs to be thoroughly researched. Most of the Society members are young people with a special interest in herps. As the name states, we are involved in keeping, breeding, and research of reptiles and amphibians. Meetings are held once each month, with lectures, discussions, and field trips in the summer. We now have about 40 members. The Society recently published the first issue of their newsletter *Zelenec* (Zelenec is the Slovenian common name for the green lizard, *Lacerta viridis*, our largest lacertid). Currently, *Zelenec* is written in the Slovene language, but an English edition is planned for the future. The first issue features articles on reptiles and amphibians of Slovenia, matamata turtles, and keeping and breeding of chameleons (with emphasis on *C. calyptratus*). Regular columns include: Editorials, Field Reports, Herp News, and Advertisments. The second issue is scheduled to be published in Spring of 1997. It will be a "Madagascar special issue." Two issues of *Zelenec* are planned for 1997. The society's address is: *Drustvo za gojenje in proucevanje plazilcev in dvozivk, c/o Matjaz Rojc, Reska 9, 1000 Ljubljana, Slovenia; e-mail: matjaz.rojc@siol.net.*

Kansas Herpetology Award Established

The Kansas Herpetological Society has announced the establishment of the Suzanne L. & Joseph T. Collins Award for Excellence in Kansas Herpetology. The Award is established in recogntion of the scientific and artistic achievements of Suzanne L. Collins and Joseph T. Collins, whose life-long study and conservation of the native amphibians and reptiles of Kansas is amply demonstrated in their extensive and excellent writings and photography, both academic and popular, about these animals. The Award will be presented once each year on the occasion of the annual meeting of the Kansas Herpetological Society before its assembled membership. The Collins Award is funded by a trust in perpetuity, and will increase in amount each year through reinvestment. During its initial year the award will minimally be $700, and may be as much as $1000. The Collins Award recipient will be chosen by the Executive Council of the KHS or a committee approved and appointed by the Council. The first Collins Award will be presented at the Silver Anniversary Meeting of the KHS in Lawrence in November 1998. For further information, contact: *Karen L. Toepfer, 303 West 39th Street, Hays, Kansas 67601, USA; e-mail: fmkt@fhsuvm fhsu edu.*

MEETINGS

Meetings Calendar

25 June–2 July 1997—40th Annual Meeting, Society for the Study of Amphibians and Reptiles; 45th Annual Meeting of The Herpetologists' League; 77th Annual Meeting, American Society of Ichthyologists and Herpetologists. Hosted by the University of Washington, Seattle, Washington, USA. *Refer to meeting announcement in this issue for details.*

2–10 August 1997—Third World Congress of Herpetology, Prague, Czech Republic. Contact: Zbynek Rocek, Congress Director, Department of Paleontology, Geological Institute, Academy of Sciences, Rozvojová 135, 165 00 Praha 6 – Suchdol, Czech Republic. Tel. (++42-2) 24311421; Fax (++42-2) 24311578; e-mail: rocek@gli.cas.cz. *Refer to meeting announcement in* Herpetological Review *27(1):4–5, March 1996 for details.*

4–7 August 1997—IV Regional Latin American and Caribbean Meeting of the Crocodilian Specialist Group, Villahermosa, Tabasco, México. Hosted by the Autonomous University Juarez of Tabasco "UJAT" (and other institutions). Contact: Biol. Beatriz Figueroa Ocana, Av. Gregorio Mendez 2006, Col. Rovirosa, Villahermosa, Tabasco 86000, México. Fax: (91) (93) 54 38 54. ; e-mail: sarriago@tukan.ujat.mx or Dr. James Perran Ross, Executive Officer, Crocodilian Specialist Group, Florida Museum of Natural History, P.O. 117800, Gainesville, Florida 32611-7800, USA. Tel: (352) 392-1721; Fax: (352) 392-9367; e-mail: prosscsg@flmnh.ufl.edu.

13–14 September 1997—Mid-Atlantic Reptile Show, Maryland State Fairgrounds. Contact: Tim Hoen, P.O. Box 201, Jarrettsville, Maryland 21084, USA. Tel. (410) 557-6879; http://www.pythons.com/mars.html.

26–28 September 1997—Midwest Regional Animal Behavior Conference, The Ohio State University, Columbus, Ohio, USA. Co-sponsored by the Zoology and Entomology Departments. Con-

tacts: Dr. Patricia G. Parker (614-292-0378; fax 614-292-2030; parker.3@osu.edu) and Brian H. Smith (614-292-0465; fax 614-292-2180; smith.210@osu.edu). Visit the meeting's site at http://www.biosci.ohio state.edu/~zoology/MRABSC97//index.htm

3–5 October 1997—Second Annual Meeting of the Canadian Amphibian and Reptile Conservation Network and the 7th Annual Meeting of the IUCN/SSC Task Force on Declining Amphibian Populations in Canada (DAPCAN), Acadia University, Wolfville, Nova Scotia. Contact: Stan A. Orchard, Chairman, CARCN/RCCAR, 1745 Bank Street, Victoria, British Columbia, Canada V8R 4V7. Tel./Fax: (250) 595-7556; e-mail: sorchard@islandnet.com.

18–19 October 1997—First International Symposium on Snakebite. Zhanjiang, People's Republic of China. Contact: Organizing Committee of the First International Symposium on Snakebite, No. 2 Cunjin Road, Zhanjiang City, Guangdong Province 524037, People's Republic of China. Tel./Fax 0086-759-3316724.

18–19 October 1997—Snake Ecology for the 21st Century. Texas Herpetological Society Fall Symposium, Camp Tyler, Texas, USA. Contact: Neil B. Ford, Department of Biology, University of Texas at Tyler, Tyler, Texas 75799, USA. Tel. (903) 566-7249; e-mail: nford@mail.uttyl.edu.

25 October 1997—Conservation Ecology of the Amphibians of the Mid-Atlantic Region, Jug Bay Wetlands Sanctuary, Lothian, Maryland, USA. Contact: Karyn Molines, Conference Chair, Jug Bay Wetlands Sanctuary, 1361 Wrighton Road, Lothian, Maryland 20711, USA. Tel. (410) 741-9330; Fax (410) 741-9346; e-mail: cswarth@umd5.umd.edu.

25–26 October 1997—Fourth Annual Conference of the Association of Reptilian & Amphibian Veterinarians. Sheraton Astrodome, Houston, Texas, USA. Contact: Wilbur Amand, VMD, P.O. Box 605, Chester Heights, Pennsylvania 19017, USA. Fax (610) 892-4813.

October 1997—III Congreso Argentino de Herpetologia, Corrientes - Argentina Asociacion Herpetologia Argentina Contact: Blanca B.A. de Avanza/Maria E. Tedesco Organizing Committe - Departamento de Biologia Anatomia Comparada - Facultad de Ciencias Exactas y Naturales y Agrimensura. Universidad Nacional del Nordeste 9 de Julio 1449 - 3400 Corrientes, Argentina.

1–3 June 1998—Biodiversity and Conservation of Amphibians and Reptiles of Tropical Forests: An International Symposium. Hanoi, Vietnam. Contact: Natalia Ananjeva (St. Petersburg, Russia), e-mail: nbanorus@glas.apc.org.

June 1998—Highlands Conference on Plethodontid Salamanders. *Refer to announcement below for further details.*

1–5 September 1998—Third International Asian Herpetological Meeting, Almaty, Kazakhstan. To receive the First Announcement and Preliminary Registration Form, please contact one of the meeting organizers: Dr. Tatjana Dujsebayeva, Department of Biology, Kazakh State University, Al-Farabi Prospect, 71, Almaty, 480078, Kazakhstan; Tel. (3272) 472677, Fax (3272) 472609, e-mail: zool@plague.almaty.kz; Dr. Natalia Ananjeva, Department of Herpetology, Zoological Institute, Universitatskaja nab., 1, Saint-Petersburg, 199034, Russia; Tel. (812) 2180711, Fax (812) 2182941, e-mail: anb@zisp.spb.su; or Dr. Theodore Papenfuss, Asiatic Herpetological Research, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA; Tel. (510) 642-3567, Fax (510) 643-8238, e-mail: asiaherp@uclink2.berkeley.edu.

The Highlands Conference on Plethodontid Salamanders

The Highlands Conference on Plethodontid Salamanders will be held in June 1998 in Highlands, North Carolina (USA), and is sponsored by the Highlands Biological Station. This meeting will follow the tradition of the First (1972), Second (1982), and Third (1992) Conferences in exploring new directions in plethodontid research. The Conference will feature invited papers, evening poster sessions, and a Symposium. All interested are encouraged to participate. Future announcements concerning Conference dates, a call for papers, and registration information will be sent only to those on our mailing list. If you attended the 1992 Conference, and if your address has not changed, you will receive announcements automatically. To be placed on the mailing list, or to update your address, please send your name, address, and numbers (phone, FAX, e-mail) to: *Plethodontid Conference, Highlands Biological Station, P.O. Box 580 Highlands, North Carolina 28741, USA or send an e-mail message to Judy Hill (HBS Admin. Asst.) at: JHILL@wpoff.wcu.edu.*

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: herpbooks@sisna.com. Comments and suggestions are also welcome.

The current contents of several herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are being listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Microevolutionary Change in *Nerodia*

Color pattern variation in Lake Erie island populations of *Nerodia sipedon* provide a classic example of microevolutionary change in which the effects of selection, gene flow, inheritance, and population history are unusually well understood. King and Lawson present a nice review of microevolution in the species in a recent paper in BioScience.

KING, R. B., AND R. LAWSON. 1997. Microevolution in island water Snakes. BioScience 47(5):279–286.

Habitat and Colonization

M'Closkey et al. studied the colonization of habitats by four species of phrynosomatid lizards (*Urosaurus ornatus, Sceloporus graciosus, S. undulatus*, and *Uta stansburiana*) to determine differences among the species in colonization, differences among habitat types in colonization, and the time trajectory of coloniza-

tion. Their study indicates there were significant habitat and census period differences in saturation.

M'Closkey, R. T., et al. 1997. Colonization and saturation of habitats by lizards. Oikos 78(2):283–290.

Crocodilian Evolution

Poe used published systematic data on crocodilians to test hypotheses of data set incongruence and phylogeny. Both molecular and morphological data sets were examined and comparisons yield interesting results.

Poe, S. 1996. Data set incongruence and the phylogeny of Crocodilians. Syst. Biol. 45(4):393–414.

Phenotypic Variation

Why some species exhibit remarkable variation among populations whereas closely related species are relatively uniform remains unclear. Summers et al. examined color variation in four species of dendrobatid frogs with different reproductive strategies. Their results suggest that strong sexual selection associated with female parental care may be a factor in the variation in *Dendrobates pumilio*.

Summers, K., et al. 1997. Phenotypic and genetic divergence in three species of dart-poison frogs with contrasting parental behavior. J. Hered. 88:8–13.

Phylogeny of Desmognathine Salamanders

Using both molecular and morphological data, Titus and Larson studied the phylogeny of desmognathine salamanders. Their results suggest that desmognathine evolution includes transformations in the direction of largest body sizes, lengthened larval periods, and greater use of aquatic habitats.

Titus, T. A., and A. Larson. 1996. Molecular phylogenetics of desmognathine salamanders (Caudata: Plethodontidae): a reevaluation of evolution in ecology, life history, and morphology. Syst. Biol. 45(4):451–472.

New *Boophis* from Madagascar

Glaw and Vences reviewed advertisement calls, morphology, diet, and reproductive characteristics of the *Boophis goudoti* group of Madagascan frogs. Their data revealed a new species, *Boophis rufioculis*, as well as other interesting aspects of the biology of these frogs.

Glaw, F., and M. Vences. 1996 (1997). Neue Ergebnisse zur *Boophis gudoti*-Gruppe aus Madagaskar: Bioakustik, Fortpflanzungsstrategien und Beschreibung von *Boophis rufioculis* sp. nov. [New results on the *Boophis goudoti*-group from Madagascar: Bioacoustics, reproductive strategies, and description of *Boophis rufioculis* sp. nov.]. Salamandra 32(4):225–242.

Heterochrony

Confusion exists with the current model and terminology of heterochrony because the model is explicitly limited to phylogenetic patterns (interspecific comparisons), but has been used for intraspecific comparisons. Because heterochrony may underlie all morphological variation and possibly is *the* developmental phenomenon producing all morphological change, it is important that descriptions of heterochronic patterns and processes be clear and precise over all levels of analysis. To this end, Reilly et al. discuss and clarify the previous model for heterochrony, reject some of the terminology and suggest alternatives, and then expand the model to include a new nomenclature for intraspecific heterochronic phenomena.

Reilly, S. M., E. O. Wiley, and D. J. Meinhardt. 1997. An integrative approach to heterochrony: the distinction between interspecific and intraspecific phenomena. Biol. J. Linn. Soc. 60:119–143.

Ecology of *Bombina bombina*

The Deutsche Gesellschaft für Herpetologie und Terrarienkunde recently published the proceedings of a symposium on the ecology and conservation of *Bombina bombina* in their journal *Rana*. The contents include 13 papers on the species' status and ecology. Listed here is the only title of the issue.

Krone, A., and K. -D. Kühnel. 1996. Die Rotbauchunke (*Bombina bombina*) Ökologie und Bestandssituation. Natur & Text, Rangsdorf, Germany. 132 pp.

Hemipene Terminology

Recent advances in the study of lizard hemipenes as a systematic character has introduced some confusion over hemipene terminology. Savage has published a paper intended to clarify definitions, resolve inconsistencies, and integrate the terminology applied to hemipenial variation for lizards and snakes into a broader scheme applicable to all squamates.

Savage, J. M. 1997. On terminology for the description of the hemipenes of squamate reptiles. Herpetol. J. 7(1):23–25.

Neural Control in Autotomized Tails

Most previous studies of tail autotomy in lizards have emphasized the energetic costs rather than the consequences for neural control of movement. Rumping and Jayne found that autotomized tails with one or more spinal segments moved longer and more vigorously than autotomized tails consisting entirely of regenerated (unsegmented) tissue.

Rumping, J. M., and B. C. Jayne. 1996. Muscle activity in autotomized tails of a lizard (*Gekko gecko*): a naturally occurring spinal preparation. J. Comp. Physiol. A. 179:525–538.

Asiatic Herpetological Research

Volume 7 of *Asiatic Herpetological Research* was recently published. This journal is recommended to anyone interested in any aspect of Asian herpetology. For more information write AHR, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA (e-mail: asiaherp@uclink.berkeley.edu).

STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES

FOURTH EDITION

JOSEPH T. COLLINS

A New Herpetological Circular from the Society for the Study of Amphibians and Reptiles

HERPETOLOGICAL CIRCULAR NO. 25

This long-awaited fourth edition lists the scientific names of all currently recognized taxa of native North American amphibians and reptiles, as well as the standardized common names for each. Thanks to the previous three editions, over 90% of the state and regional books published about these creatures since 1978 have adopted the standard common names. This edition includes an appendix for 35 alien (non-native, introduced) species, as well as publication date of description for all taxa. The latter, in conjunction with the name(s) of the describer(s), makes this an invaluable and required reference for every herpetologist interested in the 546 native species of amphibians and reptiles found in North America (north of Mexico). An appendix to 33 Hawaiian taxa is included. iv + 40 pages. ISBN 0–916984–44–3. June 1997.

This SSAR publication partially financed and cosponsored by
THE CENTER FOR NORTH AMERICAN AMPHIBIANS & REPTILES
AND DALE BELCHER

Prices:
SSAR members *before publication*.....US$7.00
Institutions and Nonmembers .....US$9.00

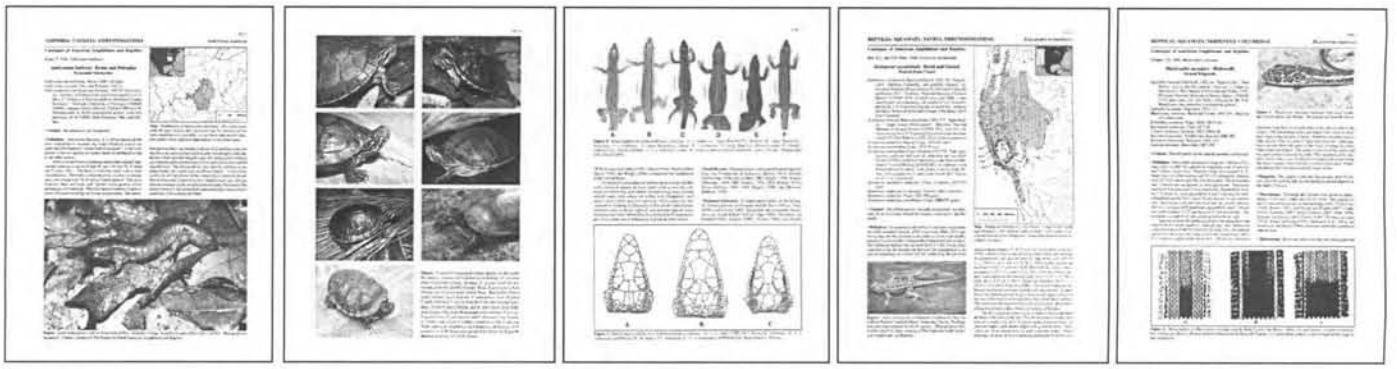
Shipping:
First copy.....US$2.00
Subsequent copies.....US$1.00

Send orders to: Dr. Robert D. Aldridge, Department of Biology, Saint Louis University, Saint Louis, Missouri 63103, USA. (*telephone*: (314) 977–3910 or –3916; *fax*: (314) 977–3658; *e-mail*: ssar@sluvca.slu.edu). Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MASTERCARD (account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request to Dr. Aldridge.

Published by the Society for the Study of Amphibians and Reptiles

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

THE CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES (CAAR) represents one of the most important long-term cooperative activities undertaken by the American herpetological community. The *Catalogue* is issued as loose-leaf accounts of taxa (1–17 letter-size pages in length). Each account, authored by a leading herpetologist, serves as a complete and current summary of the knowledge of each taxon. Further, the CAAR is not restricted to those taxa occurring within the United States, but covers the entire Western Hemisphere (North, Central, and South America, as well as the Caribbean Basin). The *Catalogue of American Amphibians and Reptiles* sets the standard for archival taxonomic publications and has been emulated by biological societies worldwide.



The *Catalogue* is issued by subscription; 20 accounts/year. All back issues (1–640), special CAAR binders, indices, and systematic tabs are also available.

Each CAAR account includes:

- Synonymy
- Content, definition, and diagnosis
- Comprehensive literature review
- Distribution map(s)
- Nomenclatural history
- Remarks
- Etymology

Many accounts also include:

- Photographs (some in color)
- Illustrations of key characters
- Taxonomic keys to species or subspecies
- Audiospectrograms

Selected pages from some 1996 accounts: *Ambystoma barbouri, Pseudemys, Cnemidophorus sexlineatus, Sceloporus occidentalis,* and *Masticophis taeniatus.*

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

Subscriptions:

Individuals	$20
Institutions	$25
Complete set: Numbers 1–640	$340 + s/h
Index to Accounts 1–400	$6 + s/h
Index to Accounts 401–600	$6 + s/h
Systematic tabs for binder	$6 + s/h
Imprinted Post Binder	$35 + s/h

(note: one binder holds about 200 accounts)

Partial sets:

Numbers 1–190	$75 + s/h
Numbers 191–410	$85 + s/h
Numbers 411–640	$210+ s/h

Subscriptions and back orders: Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MASTERCARD (account number and expiration date must be provided). Payment should be sent to Robert D. Aldridge, Department of Biology, Saint Louis University, Saint Louis, Missouri 63103, USA. Fax (314) 977-3658; e-mail: ssar@sluvca.slu.edu

New in paperback

A NATURAL HISTORY OF AMPHIBIANS

Robert C. Stebbins and Nathan W. Cohen

This is a book for all readers who want to learn about amphibians, the animal group that includes frogs, toads, salamanders, and caecilians. The class *Amphibia* contains more than 4,500 known living species, and new species are being discovered so rapidly that the number may grow to more than 5,000 during our lifetimes. Robert Stebbins and Nathan Cohen focus our attention on the "natural history" of amphibians worldwide and emphasize their interactions with their environments over time: where they live; how they reproduce; how they have been affected by evolutionary processes; what factors will determine their destinies.

"This fine book helps us to appreciate amphibians more fully and provides vital scientific information that may help us to protect them."—*Trends in Ecology and Evolution*

"The illustrations are superb [and the] line drawings are a delight. . . . A major contribution."—*The Quarterly Review of Biology*

37 halftones. 52 line illustrations.

Paper $19.95 ISBN 0-691-10251-1

LETTERS TO THE EDITOR

CITES: A Boon, Not a Boondoggle

RONALD I. ORENSTEIN
International Wildlife Coalition
1825 Shady Creek Court, Mississauga, Ontario, Canada L5L 3W2
e-mail: ornstn@inforamp.net

In his article on the dendrobatid trade, Gorzula (1996. Herpetol. Rev. 27:116–123) notes that "many scientists who claim to be affected by CITES have a less than adequate knowledge of the workings and purposes of the convention." Lamar's letter (1997. Herpetol. Rev. 28:10) in response to Gorzula displays just such an inadequacy. I am not a herpetologist, but I have had considerable experience with CITES, including attendance at CITES conferences since 1987, and I would appreciate an opportunity to clear up some of the misconceptions in Lamar's letter.

Lamar states that "CITES was never intended to be a conservation treaty." On the contrary, that is exactly what it was intended to be. The stimulus for CITES came directly from decisions taken by IUCN at meetings in the early 1960's to draft an international instrument to deal with the depradations of unregulated wildlife trade on a number of species, including spotted cats. The CITES Preamble states clearly "that international cooperation is essential for the protection of certain species of wild fauna and flora against overexploitation through international trade."

Lamar appears to be under the impression that listing decisions are made by the CITES Secretariat. This is not the case. The Secretariat, though it certainly has opinions on many issues before the Parties, is an administrative body. There is no such thing as a central council that decides listing issues. Instead, any individual Party (there are now 136 member states) can submit a proposal to add a species to either Appendix I or Appendix II, to delete a species, or to transfer it from one Appendix to another. This proposal is then voted on by the Conference of the Parties, normally at its conferences held roughly every two and one half years, with each country receiving one vote. A two-thirds majority is necessary to carry the proposal, which then enters into force ninety days after the vote.

In the case of the dendrobatid frogs, the Secretariat actually opposed the listing and asked the Parties to reconsider it after the vote was taken at the 1987 meeting. The Parties, however, refused to do so. As for the anguid lizard genus *Abronia*, there is no proposal pending to list this taxon, and CITES can hardly be held accountable for unfounded rumors.

Lamar also appears to be confused about the effect of CITES on domestic laws. CITES does not give countries power to pass domestic bans or restrictions on wildlife trade that they did not already possess. The power to pass such laws is a sovereign right. CITES merely recognizes, in Article XIV, that states signing the treaty retain the right to pass stricter laws than those necessary to carry out the treaty itself. If CITES were to disappear tomorrow, these laws would still stand, and in fact might become even more draconian. They would certainly be even less coordinated than they are now, when the CITES conferences at least provide an opportunity for country representatives to get together to discuss issues of common concern.

While I can understand the frustration some scientists may feel on having to deal with paperwork resulting either from CITES or from domestic wildlife laws, I cannot feel too sorry for the scientists Lamar refers to, who import collections into the United States without realizing that the species involved are listed as endangered under American law. The Endangered Species Act is not a secret document, any more than CITES is, and surely it is reasonable to expect importers to make the extra effort to find out what it says before bringing their specimens home.

CITES already recognizes the difference between scientific specimens and specimens in commercial trade. Appendix I species may not be traded for "primarily commercial purposes" but may be imported and exported, with the proper permits, for bona fide scientific research.

Finally, Lamar seems to view CITES as serving no greater function than to impede his research or the research of his colleagues. This short-sighted view ignores the beneficial effects of CITES on the conservation of many species, including reptiles such as sea turtles and crocodiles. These beneficial effects were recognized by an independent study of the effectiveness of CITES prepared in 1996 by the British firm Environmental Resources Management under contract to the Secretariat. CITES certainly has its flaws, but it has proven to be, on the whole, a highly beneficial and flexible instrument, and scientists would do far better working to improve its operation than carping at it from the outside. Certainly, before they express their opinions in print, they should at least make an effort to find out what the treaty is actually about.

Response to Orenstein

WILLIAM W. LAMAR
School of Sciences & Mathematics , The University of Texas at Tyler
3900 University Boulevard, Tyler, Texas 75799, USA
e-mail: wlamar@compuserve.com

It is obvious from his letter, deft and lawyerly, that Mr. Orenstein has garnered extensive knowledge of CITES, no doubt pursuant to his career. By contrast, my letter, written in a fit of pique 15 years in the making, displays considerable naiveté. For instance, I believed the various CITES officials who have told me and my colleagues the convention was a monitoring device rather than a conservation treaty. I didn't realize they, too, were confused. And I took seriously the CITES official who expressed interest in listing *Abronia*, forgetting that it remains hearsay until acted upon.

It is also obvious from his letter that Mr. Orenstein, like so many of those who decide on these issues, has never been on the receiving end of the process. The disclaimer that CITES has no effect on domestic laws is misleading. Look what happened when that local CITES office unilaterally decided that ALL fauna exported from their country required a (costly) CITES permit. At that point, their wishes—not even reflective of that country's governing body—effectively stymied local institutions and became doctrine to the universe, garnering backing from signatory countries (like the U.S., Canada, and Great Britain) whose legal systems bear no semblance to that of the initiating country. It is extraordinarily arrogant and ethnocentric, if well intended, to attempt to mate these unrelated systems. I would welcome Mr. Orenstein's "more draconian" alternative.

CITES of Honduras, responding belatedly to wanton commercial overharvesting of its herpetofauna, sought to list several pitviper species. They were competently advised that none of the suggested species, all common and unthreatened by trade, merited listing. They were also urged to look closely at the one spe-

cies they had excluded...a critically threatened endemic. Ignoring this, they proceeded with their plan.

Enter the Terciopelo, *Bothrops asper*, Central America's leading cause of snakebite and a creature so abundant it may rightly be considered a pest in many areas. Because of its listing by Honduras, you simply cannot imagine the problems encountered by one U.S. institution assisting a different Central American country that is establishing a reference collection. In order to send them a preserved Terciopelo, collected legally in that same country many years before the listing by Honduras, a "Certificate of Origin" must be obtained. Sounds easy until you try it. Of course, that also depends on the interpretations of the local USFWS office—this varies widely—but that's another story. The specimen in question has yet to make the trip back home. Anyone care to bet on its chances?

A proposed network of CITES-approved institutions pretended to ease this plan. Theoretically, any two such institutions could "traffic" more easily in museum loans, etc. In fact, many countries lack approved institutions, and in at least one case the governing authority of a country became incensed by the Secretariat's draconian procedures and declined to seek authorization. And who says the Secretariat lacks authority?

Orenstein's comments about the confusing array of non-to-slightly overlapping laws neatly dodge the issue. In fact the system is ill-coordinated, rife with pitfalls (by design?), and in need of repair. I resent the undercurrent in Orenstein's letter implying that scientists ignore positive conservation implications of the CITES treaty. In addition to generating the only solid data on which the conservation movement can rely, field biologists must witness the daily erosion not only of their careers, but also their passion—there are no truer conservationists on the planet.

I note that CITES' efficacy has been attested to by a firm under contract to...CITES. Since the Secretariat continues to duck responsibility under guise of respecting the autonomy of the 136 signatory countries, why not let EACH of them evaluate the efficacy of the treaty? That would be pretty chaotic—just like the morass scientists must deal with at present. Why not administer a test to all CITES and related officials worldwide to see how well they understand things? Orenstein has shown convincingly that CITES is all about conservation, so let's see an evaluation of how the areas it affects stack up in importance to the massive habitat destruction and internal harvesting that are depleting the species we can't even investigate. Perhaps all that money and effort could be better directed.

The crudeness of my first letter notwithstanding, I have received overwhelmingly positive response from the community. To those of you who were kind enough to have written me, I implore you to continue this dialogue, but publicly—those in power have tin ears. Maybe some day CITES will lose some of their clubbiness and seek the advice of APPROPRIATE scientists rather than expecting scientists to come to them. Oh yes, and one last thing—CITES doesn't impede my research and that of my colleagues—it virtually stops it.

POINTS OF VIEW

Scinax pedromedinai: An Unjustified Emendation of *Ololygon pedromedinae* Henle, 1991

KLAUS HENLE
Projektbereich Naturnahe Landschaften
Umweltforschungszentrum Leipzig-Halle GmbH
Permoserstr. 13, D-04318 Leipzig, Germany
e-mail: henle@rz.ufz.de

In 1991, Henle named a small species of hylid frog *Ololygon pedromedinae* in honor of Pedro Medina, the collector of the type material in the Departamento Madre de Dios, Peru. He included it in the *O. boulengeri* group. Without comment, Duellman and Salas (1991) listed the species as *O. pedromedinai*. When resurrecting the generic name *Scinax* for species formerly known as *Ololygon*, Duellman and Wiens (1992) listed the species as *S. pedromedinae*. In 1993, Duellman listed the species as *Scinax pedromedinai*, briefly stating that "The specific name was incorrectly spelled *pedromedinae* in the original description." Revising the genus *Scinax* from Amazonian Ecuador and Peru, Duellman and Wiens (1993) listed the species again as *Scinax perdomedinai*. In this publication, they justified the changed spelling of the specific name by pointing out that Pedro Medina is a man and thus the specific epithet must be masculine. To achieve this, they believed that the name must be mascularinized by emendating the name to pedromedinaus. As this action is not warranted and may contribute to nomenclatural confusion, I would like to briefly outline why this emendation has to be rejected.

The most common Latin endings of masculine words are indeed *-us* and *-is*. However, exceptions exist. For example, the Latin word for farmer, agricola, is masculine; its genetive is agricolae not agricolai. Medina is a widespread Latin name that was and still is very common in Italy, and the same rules for agricola apply to it. Whereas the emendation *-us* for a species name may be acceptable in cases in which it is derived from a non-Latin name (e.g., in *Hyla brongersmai*), such an emendation is definitely incorrect for cases derived from Latin names. For example, *Python sebae* is named in honor of the famous naturalist Seba, a man. The correct spelling for the large African python was never questioned. Meirte (1992) cites further similar cases. Clearly, the correct name of the taxon is *Scinax pedromedinae* (Henle 1991).

The Distribution of *Pituophis melanoleucus* and *P. vertebralis* in Northern Baja California, México

L. LEE GRISMER
Department of Biology, La Sierra University
Riverside, California 92515-8247, USA
email: lgrismer@lasierra.edu

Klauber (1946), Welsh (1988), and Sweet and Parker (1990) recognized four subspecies of *Pituophis melanoleucus* distributed in Baja California as follows: *P. m. annectens* ranging throughout northwestern Baja California west of the Lower Colorado Valley Desert (Sweet and Parker 1990) to 42 km east (by Mexican Highway 1) of El Rosario (Grismer and Mahrdt 1996); *P. m. affinis* ranging throughout most of the Lower Colorado Valley Desert, westward to at least Paso de San Matías (Welsh 1988; Welsh and Bury 1984); *P. m. bimaris* (= *P. vertebralis* sensu Grismer 1994a) ranging from 43 km east (by Mexican Highway 1) of El Rosario (Grismer 1994a), southward throughout central Baja California to the Isthmus of La Paz (Sweet and Parker 1990); and *P. m. vertebralis* (= *P. vertebralis* sensu Grismer 1994a) ranging throughout the Cape Region (Sweet and Parker 1990). Grismer and Mahrdt's (1996) report on a specimen of *P. m. annectens* from 42 km east of El Rosario and Grismer's (1994a) report on a specimen of *P. vertebralis* (sensu lato) from 43 km east of El Rosario in a region of homogeneous habitat, indicated that these two species were likely to be sympatric.

Surprisingly, Sweet and Parker (1990), Grismer (1994a), and Grismer and Mahrdt (1996) overlooked a specimen of *Pituophis vertebralis* (USNM 37536) collected in 1905 from El Álamo in northwestern Baja California and reported on by Klauber (1946) as part of the type series of *P. melanoleucus bimaris*. Welsh (1988) reported on the specimen but did not comment on the fact that at the time, the two "subspecies," *P. m. annectens* and *P. m. bimaris*, overlapped for ca. 173 km with no sign of intergradation. El Álamo is a small town ca. 180 km north of the northernmost record of *P. vertebralis* (Grismer 1994a; Fig. 1). As noted by Stull (1940) and Klauber (1946) and confirmed here by examination of the specimen, USNM 37536 is an "undiluted" specimen, having all the diagnostic characteristics of *P. vertebralis* and none of those of *P. m. annectens* (Table 1). The inland areas between El Álamo and the next northernmost record for *P. vertebralis* at 43 km east of El Rosario lie along the foothills of the Sierra San Pedro Mártir, and with the exception of Rancho San José (Fig. 1), are difficult to access. Therefore, it is not too surprising that a museum search (CAS, LACM, MVZ, SDSNH, USNM; museum acronyms follow Leviton et al. 1985) revealed that no additional specimens of *P. vertebralis* have been collected in this intervening region within the last 90 years, even though *P. m. annectens* is known to be present (Klauber 1946). It is possible that the locality of USNM 37536 was mislabeled and the specimen actually was collected further south as was alluded to by Klauber (1946) in his reference to this specimen being "somewhat of an anomaly" in regard to its distribution. However, other evidence does not support this. The specimen was collected by Charles Nelson and Alfonso Goldman during their overland exploration of the Baja California peninsula from March, 1905 to February, 1906. Both reported being in El Álamo on 11–12 June 1905 (Goldman 1951:37; Nelson 1922:16), which is the collection date (11 June 1905) of USNM 37536 listed in their field catalogue. During this same period, they also collected *Callisaurus draconoides* (USNM 37642; 12 June 1905) at El Álamo, a species currently known from this locality (Grismer 1994b). These observations suggest that the entry into the Nelson-Goldman field catalogue was not erroneous.

Additional evidence for the validity of the locality of USNM 37536 comes from characteristics of the specimen itself. *Pituophis vertebralis* from the northern portion of its range, beginning in the vicinity of Bahía de Los Ángeles, often lack the reddish-orange coloration on the head and in the interspaces between the black, anterior, body blotches that is prominent and always present in specimens south of Bahía de Los Ángeles. Specimens from La-

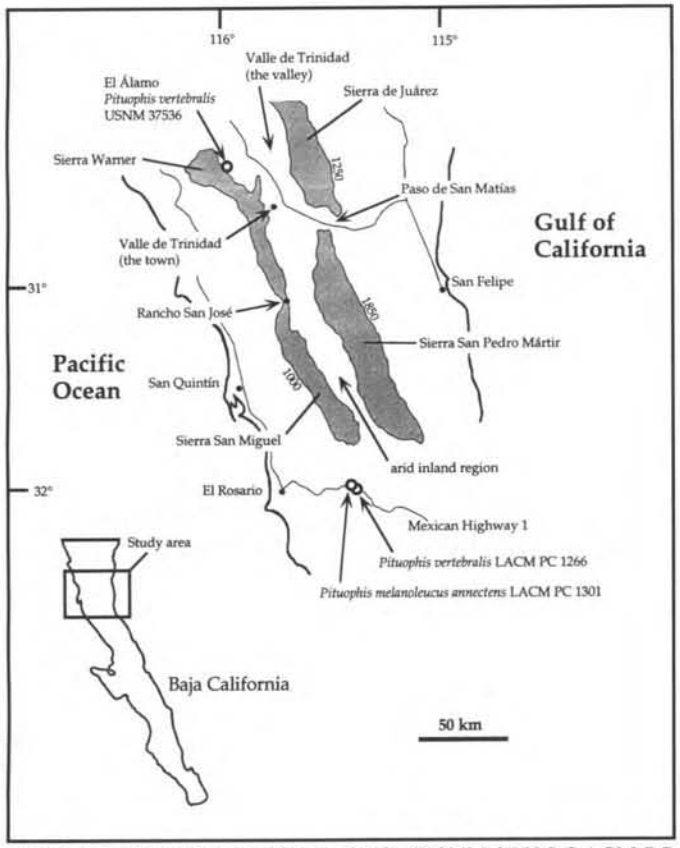

FIG. 1. Location of *Pituophis vertebralis* (USNM 37536; LACM PC 1266) and the southernmost specimen of *P. melanoleucus annectens* (LACM PC 1301) in northern Baja California, México in relation to major geographic features. Elevations are in meters.

guna Chapala (ca. 80 km northwest of Bahía de Los Ángeles) and northward lack this reddish-orange coloration, and the head and the interspaces between the anterior blotches are straw-colored. USNM 37536 also has a straw-colored head and anterior interspaces, indicating that it is at least from the northern portion of the distribution of *P. vertebralis*. (It should be noted that the reddish coloration in *P. vertebralis* is observable after many years of preservation).

Klauber (1946) was ambiguous in his suppositions concerning the possibility of intergradation between *Pituophis melanoleucus annectens* and *P. vertebralis*. He stated that it was "very doubtful" (p. 11) that the two taxa would intergrade, but that a specimen from Valle de Trinidad (FMNH 1394; = CNHM 1394) was "possibly" an intergrade (p. 28) between the two. Welsh (1988) and Sweet and Parker (1990) cited Klauber (1946:11) in stating that the two did not intergrade in northwestern Baja California. I have examined FMNH 1394 and find that it lacks the diagnostic characteristics of *P. vertebralis* but falls well within the range of the diagnostic characteristics reported for *P. m. affinis* and *P. m. annectens* (Table 1), and I suspect it may be an intergrade between these two forms. Welsh and Bury (1984) reported on a probable intergrade between *P. m. affinis* and *P. m. annectens* from 9.1 km east of Paso de San Matías. Additionally, I have made field observations on two putative intergrades between these two forms in the same region, and I currently am examining a large series of *Pituophis* from throughout Valle de Trinidad (on which I will report later), which also contains what appear to be intergrade specimens.

The ecogeography of other species also supports the presence of *Pituophis vertebralis* at El Álamo. Many xerophilic taxa occurring in the more arid, central regions of the peninsula are able to extend northward into cismontane, northwestern Baja California through a narrow, arid, inland zone lying immediately west of the Sierra San Pedro Mártir and east of the Sierra San Miguel (Fig. 1). The Sierra San Miguel runs parallel to the Sierra San Pedro Mártir for ca. 47 km where it converges in the north with the Sierra Warner. Together, these ranges comprise the southwestern margin of Valle de Trinidad and at which point the latter narrowly merges with the arid, inland regions to the south. The Sierra San Miguel buffers this zone from the maritime influence of the Pacific Ocean, which leaves much of coastal, northwestern Baja California cool, foggy, and windswept for much of the year. As such, many xerophytic plants of the more arid, southerly Vizcaíno Region extend into cismontane, northwestern Baja California through this corridor (Shreve 1936). Similar distribution patterns have been noted in birds (Short and Crossin 1967) and reptiles (Grismer 1994c; Welsh 1988). Reptiles that fit this general pattern are *Crotaphytus vestigium,* which extends northward to at least Rancho San José (Welsh 1988); *Gambelia copeii*, which extends northward into Valle de Trinidad and continues on into southern San Diego County (McGuire 1996); *Xantusia vigilis,* which extends northward to at least Mike's Sky Rancho (Welsh 1988); and *Chilomeniscus cinctus,* which ranges as far north as Valle de Trinidad (Welsh 1988). Welsh (1988) stated that the presence of *C. cinctus* in Valle de Trinidad may be indicative of its occurrence in sandy habitats of the southern Colorado Desert east of the Peninsular Ranges. It is more likely that this area is occupied instead by *Chionactis occipitalis*, as based on a specimen reported by Grismer (1989) from south of San Felipe, three specimens I observed in Paso de San Matías, and the fact that no specimens of *Chilomeniscus cinctus* have been collected from northeastern Baja California (Grismer 1994b).

Therefore, based on all the evidence presented above, the most logical conclusion is that *Pituophis vertebralis* occurs at El Álamo in the western end of Valle de Trinidad, and that it is probably sympatric with *P. melanoleucus annectens* for ca. 180 km along the western foothills of the Sierra San Pedro Mártir. Only additional collecting in this poorly explored area will reveal the geographic nature of the distribution of *P. vertebralis* (allopatric or continuous) in this portion of its range.

Acknowledgments.— I thank R. McDiarmid, R. P. Reynolds, and S. Gotte (USNM); A. Leviton and J. Vindum (CAS); H. Voris (FMNH); R. Bezy (LACM); S. Sheldon (SDSNH); and D. Wake (MVZ) for the loan of specimens and/or records. I thank J. Boundy, B. Hollingsworth, C. Lieb, and J. McGuire for comments on the manuscript.

Courtship Behavior Provides Additional Evidence for a Monophyletic *Pseudemys*, and Comments on Mesoamerican *Trachemys* (Testudines: Emydidae)

MICHAEL E. SEIDEL
Department of Biological Sciences, Marshall University
Huntington, West Virginia 25755, USA
e-mail: M043021@MARSHALL.WVNET.edu

and

UWE FRITZ
Staatliches Museum für Tierkunde
Forschungsstelle, Augustusstrasse 2, D-01067 Dresden, Germany

The southeastern United States has a rich diversity of aquatic turtles in the family Emydidae. Gaffney and Meylan (1988) assigned to the subfamily Deirochelyinae six closely related, and often sympatric genera (*Deirochelys*, *Graptemys*, *Malaclemys*, *Chrysemys*, *Trachemys*, and *Pseudemys*), from this region. However, relationships among these turtles have remained controversial. The generic arrangement of painted turtles (*Chrysemys*), sliders (*Trachemys*), and cooters and red-bellied turtles (*Pseudemys*) has had an especially eventful history that has variously seen them recognized as one, two, or three genera (see Seidel and Smith 1986, for a review). Recently, however, most authors have returned to Agassiz' (1857) concept of three genera following the broad-based analysis of Seidel and Smith (1986). This arrangement has received nearly universal acceptance (Ernst et al. 1994), but see Legler (1990). Phylogenetic relationships among these genera are currently being examined by nucleic acid analysis (Bickham et al. 1996; Starkey et al. 1995) and morphological comparisons (Seidel and Meylan, ms.). Observations of courtship behavior, summarized here, provide further evidence that species of *Pseudemys* (sensu stricto) constitute a single evolutionary lineage, separate from *Trachemys*, *Chrysemys,* or map turtles—*Graptemys* (Fritz 1991).

Despite their differences, *Pseudemys* and *Trachemys* possess many morphological and ecological similarities. Both are moderate-sized (200–450 mm carapace length) aquatic turtles with well developed basking habits. Their food preferences are similar but cooters and red-bellied turtles are more herbivorous than sliders, especially as adults. *Pseudemys* and *Trachemys* also share with *Chrysemys* and *Graptemys* an elaborate pattern of aquatic courtship involving "titillation" in which a male extends his forelimbs and vibrates his elongated claws near or against a female's eyes. Anecdotal or rudimentary evidence of this also has been observed in *Malaclemys* (Sachsse 1984) and juvenile *Deirochelys* (Krefft 1955).

Titillation courtship behavior tends to be stereotypic within species, but subtle differences in claw vibration or head movements may occur between species (Vogt 1993). The widespread presence of this behavior in the Deirochelyinae suggests that its absence or reduction in some species is a degenerate (derived) condition. It probably has "regressed" independently in at least two separate lineages, including map turtles (e.g., *G. geographica*: Vogt 1980; *G. ernsti*: Shealy 1976) and sliders (*T. scripta* sensu lato). Several authors have reported absence of titillation courtship in mesoamerican and South American sliders (Davis and Jackson 1973; Fritz 1990; Legler 1990; Medem 1975; Moll and Legler 1971; Pritchard and Trebbau 1984; Rosado 1967). This, along with morphological differences, has prompted some authors to propose that neotropical *Trachemys* be separated from *T. scripta* into one or more additional species (Fritz 1990, 1991; Seidel 1989; Vanzolini 1995; Ward 1984; Wermuth and Mertens 1977). It is noteworthy that residual titillation behavior may persist in these turtles in another form. One of us (UF) has made extensive observations on captive courtship behavior in *T. ornata venusta*[1] collected at Tlacotalpan, Veracruz, México. Over a period of seven years, six males used only intensive head-nodding motions when courting a female. However, on several occasions, males were observed vibrating their foreclaws at each other during apparent aggressive encounters. Male-male or juvenile interactions such as this have previously been viewed as courtship or play (Cagle 1955; Kramer 1989; Morris 1976; Petranka and Phillippi 1978), whereas they may actually represent displacement or threat gestures related to aggression. In any case, observations on *T. o. venusta* behavior further suggest that reduced titillation is a degenerate condition.

In most emydid turtles known to utilize foreclaw titillation, the male faces the female head-to-head and extends his forelimbs. This has been observed at least in *Chrysemys picta bellii* (Taylor 1933); *C. p. picta* (Ernst 1971); *Trachemys s. elegans* (Jackson and Davis 1972a; Molina 1992); *T. s. scripta* (Fritz 1991; Lovich et al. 1990); *T. s. troostii* (Fritz 1991); *T. stejnegeri*, *T. decussata*, *T. terrapen*, *T. decorata* (Seidel 1988, and pers. observ.); *Graptemys barbouri* (Wahlquist 1970); *G. ouachitensis*, *G. pseudo-geographica* (Ernst 1974; Vogt 1980, 1993); *G. flavimaculata* (Vogt,1978); *G. nigrinoda* (Vogt 1978; but see Lahanas 1982); and *Malaclemys terrapin* (Sachsse 1984).

A major variant of foreclaw titillation is seen in *Pseudemys*. In cooters and red-bellied turtles, the male does not approach the female from the front or face her during forelimb vibration; instead, he positions himself above the female, facing the same direction while extending his head and forelimbs down near her eyes and then vibrating his claws. This has been reported for *P. nelsoni* (Kramer 1986; Kramer and Fritz 1989), *P. concinna suwanniensis* (Jackson and Davis 1972b), *P. c. concinna* (Fahey 1987), *P. c.*

[1] Application of the name *T. ornata* here is the decision of U. Fritz.

hieroglyphica (= *concinna*) (Carpenter 1979), *P. c. mobilensis* (= *concinna*) (Cagle 1950), *P. c. floridana* (Obst 1985), *P. peninsularis* (White and Curtsinger 1986), and *P. texana* (Fritz 1989). Obst (1988) reported this variant in *P. rubriventris*, but that may be a reference to *P. nelsoni* because he treated the two forms as conspecific.

In all species of *Pseudemys* for which courtship behavior has been reported, the male vibrates his foreclaws toward the female from above; this behavior has not been reported for any other genus of deirochelyine. Therefore, this may be considered a shared derived character (synapomorphy) for the species of *Pseudemys*. This condition may have evolved more than 20 million years ago (Miocene) when *Pseudemys* presumably diverged from a basal ancestor related to *Trachemys*, *Graptemys*, *Malaclemys*, and/or *Chrysemys* (Fritz 1991; Seidel and Jackson 1990). It may have been an important step in maintaining reproductive isolation in an area of frequent sympatry. Species within *Pseudemys* appear to be closely related (Seidel 1994), but examination for subtle courtship differences within this genus could be informative. In conclusion, the authors would welcome communication from anyone who has observed courtship (in nature or captivity) of deirochelyine turtles not reported here. Observations of courtship in *P. rubriventris*, *P. gorzugi*, *P. alabamensis*, and *Deirochelys* would be especially interesting.

Acknowledgments.—We thank John Iverson for helpful comments on an earlier draft of the manuscript.

Documenting a snake species' diet and foraging behavior is often the first step in the development of an understanding of its ecology (Greene 1992). The significance of diet and foraging data lies in what they may convey regarding habitat use (Reinert et al. 1984), movement and activity patterns (King and Duvall 1990), reproductive ecology (Keenlyne and Beer 1973), and community structure (Gregory 1978). With respect to endangered species, this information may be particularly valuable (Greene 1994).

We report observations on the foraging behavior of free-ranging Jamaican boas (*Epicrates subflavus*). Regarded as "vulnerable" (Groombridge 1993), the endemic Jamaican boa persists in 8–9 isolated local populations occupying forested habitat distributed across the breadth of the island (Gibson 1995; Oliver 1982). As part of a pilot study of the species' behavioral ecology, we conducted fieldwork at Windsor on the northern periphery of the Cockpit Country, Trelawny, western Jamaica. Between 22 October and 11 November 1995 we searched for snakes daily in the surrounding wet limestone forest and coffee and banana fields. In the evening we surveyed the main entrance to Windsor Great Cave (150 cm wide by 200 cm high) and another large cave opening (ca. 10 m by 10 m) where boas have been reported foraging on emerging bats (R. Kerr, pers. comm., Vareschi and Janetzky, *in press*).

We visited Windsor Great Cave at 1750 h on 22 October and found a juvenile (95 cm SVL, 320 g) female boa hanging from vegetation growing on the cliff above the mouth of the cave. About two-thirds of her length was hanging straight down in the flight path of emerging bats. Her ventral or lateral surfaces faced the entrance (never the dorsal surface) and the head was cocked very slightly dorsally with the mouth closed (Fig. 1). Goodwin (1970) reported three species of bats (*Chilonycteris* [*Pteronotus*] *macleayi grisea, C.* [*Pteronotus*] *p. parnellii, Monophyllus r. redmani*), totaling many thousands, from this cave. Neither the snake nor the bats seemed disturbed by our presence and the use of dimmed headlamps. Over the next hour, the snake made many attempts to capture bats that were either emerging from, or re-entering the cave. We carefully searched the vegetation around the cave mouth but found no other snakes. At 1850 h we captured the boa for examination and temporary marking with paint. She was released at the capture location at 1000 h the following day.

We surveyed Windsor Great Cave each evening between 23 and 28 October but saw no other boas. On 29 October at 1825 h we found the same individual *E. subflavus*, again hunting for bats at the cave. We carefully monitored her foraging behavior for the next 1 h 45 min. Throughout the observation period she exhibited the same foraging posture we had witnessed the first evening. No tongue flicking was observed. When bats passed very close or actually collided with her, she actively attempted to capture them by swinging upward with her mouth open wide. Bat activity fluctuated over the period of our observation and this was reflected by the number of capture attempts made by the snake. During the first 40 min of observation she made 100 capture attempts (2.5 attempts/min), whereas she took 60 min to make the next 100 capture attempts (1.6 attempts/min). Despite making over 200 attempts she never captured a bat during our observation period. We visited both cave openings five more times, but saw no other boas.

During our fieldwork we made three additional observations relating to the foraging behavior and diet of Jamaican boas. On 27 October we found a fresh boa scat deposited on a rock pile located in wet limestone forest habitat. Upon close inspection, the scat appeared to be composed almost entirely of rat (*Rattus rattus*) hair. On the morning of 28 October we captured an adult (132 cm SVL, 920 g) female boa who was apparently foraging for rats in the home of a local resident. Finally, at 1500 h on 2 November we captured an adult (185 cm SVL, 2040 g) male boa in an overgrown banana field. The snake was perched 2 m off the ground in a sapling (2 cm DBH), with its head and neck in a typical "S-shaped" striking posture. We believe that the snake was waiting to ambush birds, which we noted had been feeding nearby on ripe bananas. We captured this snake and returned to the field station where it was force-fed a 10 g radio-transmitter. The snake was then released at the capture site at 1400 h the following day. We relocated this snake in forest habitat daily over the next eight days. On three of these days we found the snake in an ambush foraging posture coiled among terrestrial tank bromeliads (*Aechmea paniculigera*) on the forest floor or perched in a sapling (2 cm DBH) 1.5 m off the ground. Bird species that we commonly en-

countered in this habitat included *Saurothera vetula, Turdus aurantius*, and *Dendroica caerulescens*.

Bat predation by West Indian *Epicrates* boas has been documented on a number of occasions (e.g., *E. angulifer* and *E. inornatus*, Hardy 1957; Rodriguez and Reagan 1984, respectively) but rarely for the Jamaican boa (Vareschi and Janetzky, *in press*). However, according to residents of the Windsor area and other visiting researchers, it is a behavior that is not uncommon. Indeed, we have received reports of boa sightings in at least three separate cave systems (Windsor Caves, Trelawny; Green Grotto Caves, NW St. Ann; St. Clair Cave, N St. Catherine) and have observed boas at two of these locations ourselves.

Large permanent bat roosts represent predictable, high density, but localized prey sources, which at least three species of *Epicrates* exploit. It is therefore quite plausible that other members of the genus (e.g., *E. striatus*) also forage in this manner. Nevertheless, in the vicinity of Windsor Cave, Jamaican boas also appear to prey upon birds and rodents (Cruz and Gruber 1981) which, superficially, appear less reliable sources of prey than roosting bats. The relative costs and benefits of prey choice by Jamaican boas are unclear.

The ease with which boas may be observed foraging on bats suggests that these predator-prey systems could prove to be fruitful models for researching foraging theory. In addition, the susceptibility of such systems to human disturbance warrants further investigation of the importance of bat predation for endangered West Indian boas.

Acknowledgments.—We thank R. Alvo, L. Downer, S. Williams, and Dongo for field assistance, R. Kerr and staff at Hope Zoo for logistical support, the Canadian Parks Service for equipment loans, and Jersey Wildlife Preservation Trust, Wildlife Preservation Trust Canada, and the Monty Wood Tropical Conservation Fellowship for financial support. Comments by J. Delahanty, B. Henderson, W. Janetzky, and A. Rodriguez-Duran improved the manuscript.

Abnormalities in Embryos from a Wild American Alligator (*Alligator mississippiensis*) Nest

LOUISE HAYES-ODUM*

and

JAMES R. DIXON

Department of Wildlife and Fisheries Science, Texas A&M University
College Station, Texas 77843, USA

**Present address: Living Resource Center, 11833 Chimney Rock Road*
Houston, Texas 77035, USA
e-mail: hayesodu@tenet.edu

Congenital malformations in crocodilians have been summarized by Ferguson (1985) and include skeletal, visceral, color, CNS, and craniofacial anomalies, plus double yolks, twinning, and axial bifurcation/partial twinning. Abnormalities in crocodilian embryos may be due to the female (usually very young or old) producing damaged embryos or to incubation conditions such as extreme temperatures, unsuitable hydric or gaseous environments within the eggs, or the eggs not being oriented at the proper axis (Ferguson 1985).

While conducting a study on American alligator (*Alligator mississippiensis*) nests at the J. D. Murphree Wildlife Management Area, Jefferson Co., Texas, USA, for the purpose of correlating nest temperatures with resulting sex ratios, we discovered one nest with extremely high temperatures. An examination of the young from the nest revealed that all possessed externally visible deformities.

The nest was composed of common reed (*Phragmites communis*) and soil. Nest temperatures were monitored on an hourly basis from 30 June–22 July 1988, using a self-contained temperature recording device placed within the nest with a probe leading to the center of the nest cavity. The mean temperature recorded by the device during this period was 32.0°C, but the values for the individual temperatures, and the high and low temperatures were lost due to problems encountered when transferring the data into a computer. However, immediately before opening the nest to insert the temperature recording device, a Miller and Weber cloacal thermometer was slid into the unopened nest cavity and registered at 36°C. (The temperature recording device and cloacal thermometer were known to be accurate to the nearest 0.5°C of each other). Eight other nests being monitored during this study had mean temperatures ranging from 26.0–31.0°C and high temperatures of 30.0–32.5°C. The eggs were removed from the nest four days prior to the onset of hatching, and were numbered consecutively from top to the bottom of the nest in a clockwise direction. All eggs appeared normal externally with the exception of two rotten eggs (one with a concretion on the end of the shell and the other flat on one side). Several eggs began to hatch on 15 August 1988, and the remainder were opened the following day. Of 48 eggs, six were rotten, 19 contained early dead embryos (embryos too small to be seen), two contained late dead embryos (visible, usually 25 days of incubation or more), four contained full-term dead embryos (fully developed, but found dead when the egg was opened), and 17 contained full-term live embryos.

TABLE 1. Individual measurements (cm) on deformed *Alligator mississippiensis* hatchlings from 1988, Nest 7 at the J. D. Murphree Wildlife Management Area, Texas. UJAW (Upper Jaw): 1 = normal, 2 = deformed. LJAW (Lower Jaw): 1 = slight deformity, 2 = intermediate deformity, 3 = extreme deformity. Tail: 1 = straight, 2 = deformed; L = twisted to left, R = twisted to right. Mean value for UJAW = 1.8 (SD = 0.1); mean for LJAW = 1.5 (SD = 0.1).

* undifferentiated or unable to determine due to poor condition.
** kept alive.

All full-term alligators had varying degrees of mandibular hypoplasia, an abnormally short lower jaw. Nine animals had caudal scoliosis, and four of these also possessed unilateral maxillary hypoplasia in which one side of the upper jaw was shorter than the other. Sixteen of the live hatchlings were sacrificed (one was kept alive), and these and the four full-term dead alligators were examined internally and had one of their gonads removed for histological confirmation of sex. The animals possessed normal looking thoracic and abdominal organs, and a thymus and all aortic arches were present and in appropriate locations. The most deformed individuals were females or were more "female-like" in terms of histological gonad appearance; they were runts and had all of the upper jaw and the most extreme lower jaw abnormalities. The gonads identified as male in this clutch were definitive, but some of those denoted as female were largely undifferentiated. Sex, degree and/or presence of jaw and tail deformities, direction that deformed tails or upper jaws were twisted, and measurements of total (TL), snout-vent (SVL), upper jaw (UJAW), and lower jaw (LJAW) lengths are listed in Table 1.

The alligator kept alive was a male (confirmed by the presence of a penis) with an intermediate mandibular deformity, normal maxillae, and a kinked tail. When he was several days old, he was placed in an outdoor enclosure with several yearling alligators. He exhibited normal behavior, with the exception of being slightly off balance when diving into the water. He fed well on an insect diet, but often was unsuccessful grabbing the prey on the first attempt due to the jaw abnormality. By 1990, the deformities had lessened in severity of appearance, his clumsiness in diving and feeding was no longer apparent, and he began feeding on young mice. The following year he began feeding on adult mice and had no difficulty in quickly swallowing them whole. In June 1994, he began bellowing. His growth was stunted and his total length was only 84.5 cm as of July 1996.

The type of anomalies present in the alligators, coupled with the temperature data, suggest that they were heat induced (Ferguson 1985). The females found in this nest had the most severe anomalies. Alligators have been found to have temperature sex determination displaying a female-male-female pattern with females occurring at the low and high temperatures (Lang and Andrews 1994). Hence, it is unclear why there were males in the nest, presumably exhibiting high temperature induced abnormalities, when all females might be predicted to occur. One possible explanation is that sex was determined prior to high nest temperatures. If the females were produced in the warmest portions of the nest, then these areas might be expected to overheat to a greater extent than the male producing areas, thus causing more severe deformities in the females.

We doubt that the most severely deformed alligators (those with a maxillary deformity) from this clutch would have been capable of surviving in the wild. They were the smallest (<16 cm TL), weakest individuals, and had caudal scoliosis and at least an intermediate degree of mandibular hypoplasia. Because the animal with the intermediate mandibular deformity and caudal scoliosis is thriving, it seems possible that such an individual could survive in the wild. However, due to its stunted growth, we think it unlikely that it will ever become reproductively active. The sacrificed specimens were deposited in the Texas A&M Wildlife Research Collection.

Acknowledgments.—The temperature measuring and recording device was designed for this project by students in the Texas A&M University Department of Engineering Technology under the supervision of R. Puckett. Thanks is extended to D. Owens for the use of his lab and supplies for the histological preparation and sharing his knowledge of histological techniques. T. Wibbels and H. Austin shared their time and expertise regarding histological identification of reptile gonads, and R. Robinson

examined the specimens at the macroscopic level. K. Wood assisted in taking the various measurements and recording associated data. R. A. Odum offered suggestions on the manuscript. Partial funding for this research was provided via a grant from the Texas Herpetological Society. All research was approved by the Texas A&M University Animal Welfare Committee and was conducted under the provisions of a Texas Parks and Wildlife Department scientific permit.

TECHNIQUES

Scanning Electron Microscopy of High Resolution Casts for the Study of Tooth Surface Morphology in Snakes

KATE JACKSON
Museum of Comparative Zoology, Harvard University
Cambridge, Massachusetts 02138, USA
e-mail: kjackson@oeb.harvard.edu

Scanning electron microscopy (SEM) has been used to visualize detail in tooth surface morphology for studies of snake systematics (e.g., Jackson and Fritts 1995, 1996; Rasmussen 1975) and functional morphology (e.g., Kochva and Meier 1986; Mebs et al. 1994; Savitzky 1981). Although SEM allows the morphology of snake teeth to be examined at high magnifications, it has the disadvantage of being destructive; maxillae or individual teeth must be removed from the specimen, mounted on stubs, and sputter-coated with gold. The destructive nature of this technique limits its usefulness for the study of type or rare material and for studies involving large series of specimens.

The following technique was developed by Myers et al. (1995) for the study of mammalian taste papillae, but may be applied equally well to the study of snake teeth. Here, I will describe its use to make a high resolution cast of the grooved posterior fang of the brown tree snake (*Boiga irregularis*).

The mouth of a fluid-preserved specimen (*B. irregularis*, THF 9709) was blotted dry, and the left posterior fangs were exposed. A droplet of Reprosil hydrophilic vinyl polysiloxane impression material (light body) (Dentsply International Inc., Milford, Delaware 19963-0359, USA) was applied to the corner of the mouth (so as to completely cover the fangs) and allowed to dry (Reprosil is mixed with a catalyst immediately prior to application, and takes approx. 7 min to harden to a rubbery consistency). The solidified Reprosil impression was then peeled off the fangs and stored at room temperature for 24 h to allow for degassing. A cast of the fangs was made by filling the impression with Spurr's low viscosity embedding medium (firm mixture) (Bozzola and Russell 1992), using a $23G^3/_4$ hypodermic needle and a 1cc syringe. After the cast had been allowed to cure for 24 h at 70°C, the Reprosil impression was peeled off.

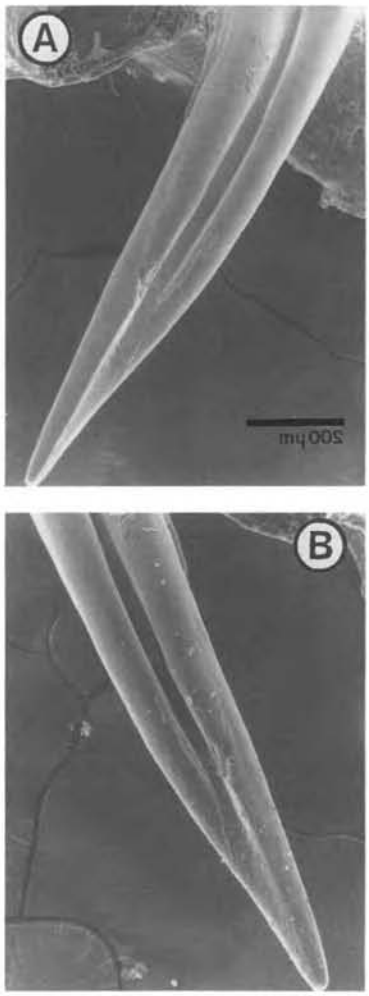

FIG. 1. SEM image of (A), the grooved posterior fang of *Boiga irregularis*, and (B) a high resolution cast of the same specimen.

For the purpose of comparison between cast and original fang, the left maxilla was later dissected out of the specimen. Both the cast and the original fang from which it was made were mounted on a stub, sputter-coated with gold, and examined using a JEOL 6400 scanning electron microscope at an acceleration voltage of 15 kV. The resulting SEM images of the original fang (Fig. 1A) and of the high resolution cast of the same fang (Fig 1B) are shown below. This technique has many potential applications beyond the study of snake teeth, and could be used for the non-destructive study of the surface morphology of any hard or soft tissue (e.g.. scales, hemipenes, etc.).

Acknowledgments.—I thank T. H. Fritts (National Museum of Natural History) for specimens, and S. Andaluz, J. Cadle, and H. Robeck for comments on the manuscript.

Effective Predator Excluders for Turtle Nests

TERRY GRAHAM
Department of Biology, Worcester State College
Worcester, Massachusetts 01602, USA
e-mail: t1graham@mecn.mass.edu

In 1983, alarmed by the destruction of redbelly turtle *(Pseudemys rubriventris)* eggs by marauding mammals, I sought a means of physically "excluding" these predators from access to turtle nest chambers. The method of nest cage construction and installation that I describe has been extremely effective over the past 13 years.

Cages are made of black or dark green 1.2 cm x 2.5 cm vinyl-coated wire mesh that can be purchased in 30 m rolls about 45–50 cm wide. Using metal shears, wire sufficient to produce a one-piece rolled cylinder 50 cm in diameter is cut. The cut edges of the mesh are then fastened together with 1.2 cm stainless steel hog rings, forming an open-ended cylinder. Finally, another piece of mesh just large enough to fit the area of one open end is cut and hog-ringed into place. After this square top piece is ringed securely around the circular edge of the mesh cylinder, its four overhanging corners are bent downward out of the way. Smaller mesh is preferred for protecting the nests and retaining the young of smaller species (e.g., mud and musk turtles).

FIG. 1. Circular trench and trenching tool.

A circular imprint of the cage rim is obtained by placing the cage down over the nest, after first aligning the center of the cage with the nest. The cage is then pressed into the soil and twisted so as to leave a clear imprint of the perimeter. This imprint serves as a template for digging a circular trench 30 cm deep around the nest (Fig 1). A good trenching tool for this job is a small mattock (available in military surplus stores). Care must be exercised in digging to avoid disturbance to the cylinder of substrate containing the nest chamber. In sandy soils this digging can be accomplished in 10–15 min, but in gravelly or rocky soils the time required will be longer. Large rocks and tree roots can be especially troublesome and difficult to remove without disturbing the integrity of the nest chamber. It is sometimes impossible to remove them safely, so it is recommended that such obstacles be left in place and that the bottom edge of the cage be cut to fit over them. The mesh cage is lowered into the trench, which is then backfilled with loose soil to ground level. The surface soil around the cage can then be tamped down by stepping firmly on it all around. If excavation and cage installation are done properly, the depth, surface, and overall integrity of the nest will not be compromised.

FIG. 2. Completed cage installation; pair of steel cage extractors to the right.

The completed installation (Fig. 2) leaves about 20 cm of the cage exposed to act as an above-ground holding pen for emerged hatchlings. Young can be removed through the top if the mesh cover is first unringed along one side, and then folded back. Finding it somewhat difficult and time consuming to open cages, I devised cage removal tools that allow me to extract the intact cage from the ground. A pair of steel hooks, on the idea of stevedore's hooks, were fashioned from 0.7 cm rod (30 cm long) welded to the center of a 12 cm piece of heavier (1.8 cm) rod serving as a handle. The rod tip was then heated, hammered flat for about 3 cm, and bent in a "U" to form a hook. Gripping opposite edges of the cage top with two of these hooks, I am able to withdraw the cage from the ground by applying a steady, upward pull. In cases where cages refuse to budge, I pull on one hook until the cage is loosened and then pull alternately on each hook, rocking the cage back and forth out of the ground. Because the vinyl coating prevents the buried mesh from rusting, these cages can be stockpiled and reused.

Finally, if these nest cages cannot be checked frequently during the period of emergence, a shaded refuge for the young must be provided inside. A piece of burlap or other coarse fabric can be ringed to the side of the cage to block the midday sun. If this awning shades the center where the nest is situated, it may cool the nest and alter hatchling development, sex ratio, and emergence. Another approach might be to install a hatchling hiding box in each cage, but the simplest strategy is to check the cages frequently to prevent heat and dessication stress to emerged young.

Acknowledgments.—I thank Bob Alberghini for fabricating my cage extractors, and am indebted to Paul Lefrancois, Norman Bell, Andy Graham, Paul Metcalf, and Bruce Ericson for assembling and installing dozens of these cages over the past decade. Wire mesh for the cages was provided by the Massachusetts Division of Fisheries and Wildlife.

An Improved Technique for Formalin Fixation of Large Vertebrates

MICHAEL R. J. FORSTNER

While injection of formalin solution by hand-held syringe (Anderson 1965; Simmons 1987) is easy and effective, it can be both inefficient and laborious when preserving larger specimens. Turtles are especially difficult to prepare and they are often inadequately preserved because of the difficulty with injecting sufficient preservative into the body cavity. Turtles preserved using hand-held syringes seldom have everted penes and the head and limbs often remain tightly enclosed within the shell. We improved this method by using a modified garden sprayer for the pressurized injection of formalin (Fig. 1). Using our technique, the preservation of 173 previously frozen turtle specimens required only 4 h, an average of 3 min per turtle. We estimate the time required by manual injection would have approached 22 h. Our technique resulted in the successful eversion of nearly 80% of the penes and produced effective limb and neck extension in 95% of specimens.

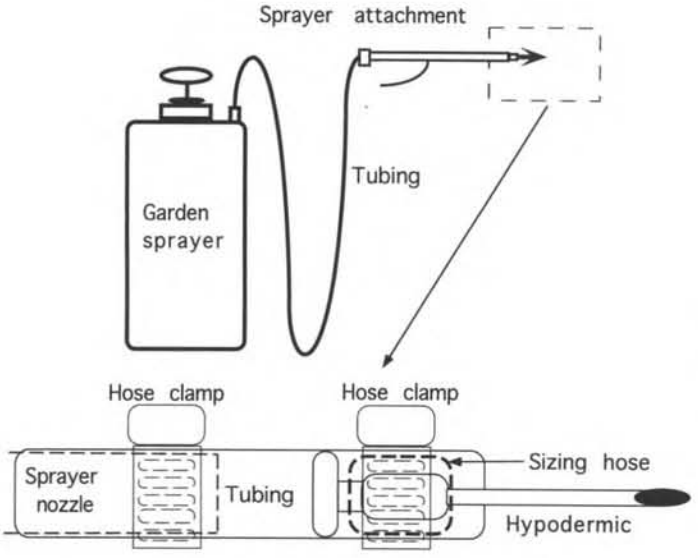

FIG. 1. Pressurized formalin injection sprayer. Dashed box provides alignment and assembly component detail for the hypodermic attachment.

The sprayer (Fig. 1) is available at most hardware stores; currently we use a Root:Lowell Heavy Duty Model (No. 1996) with a brass nozzle. Other materials required include tubing (Fisher 14-176 series), injection needles (stainless steel Fisher 14-825 series), and an assortment of hose clamps (Fisher 14-198 series). The needle assembly consists of clear, chemical-resistant, tubing (12–16") with an appropriate gauge needle inserted and clamped at one end. This assembly may require additional smaller-diameter tubing for accurately "sizing" smaller gauge needles and assuring a pressure-tight seal (Fig. 1). Assembly is straightforward: clean the sprayer tank with a hot water rinse, remove the nozzle from the sprayer delivery wand, and attach the hose assembly.

The entire apparatus can be modified from one gauge needle to the next in a few minutes. We have found that an assortment of hose and needle combinations, chosen to fit a variety of vertebrates, is most useful. The entire cost of the unit is less than US $50. All museum and field assistants must wear proper eye and clothing protection when using the formalin sprayer.

Acknowledgments.—We thank K. Vaughn, the staff of the Texas Cooperative Wildlife Collection, and S. K. Davis for their contributions to the development of this apparatus.

Radiotelemetry has become an important technique for studying species movements and, while externally-attached transmitters have been used on amphibians (Richards et al. 1994), our initial experiments with harnesses on *Dicamptodon tenebrosus* resulted in harness slippage and skin irritations. Transmitters have been implanted effectively in several amphibian species (Richards et al. 1994) and implantation methods for large aquatic salamanders have been described (*Cryptobranchus alleganiensis*; Stouffer et al. 1983). Here we describe the surgical method (modified from Stouffer et al. 1983) we used for larval *D. tenebrosus*, translocated to the upper Sacramento River from connecting tributaries in Siskiyou and Shasta counties, California, USA, and discuss factors affecting the incision healing rate of an aquatic salamander.

During May and June, 1995, 19 *D. tenebrosus* larvae (156–233 mm total length, 39.5–72.0 g) were captured; transmitter weight (2.5 g) was limited to < 6.5% of body weight. All 19 salamanders were implanted with SM1 transmitters (2.5 g, 8 mm x 10 mm 21 mm, AVM Instrument Co.) that had been potted in dental acrylic. Salamanders were anesthetized by submersion in a 0.01% solution of benzocaine. Anesthetized animals were then placed right side down in a foam-lined plastic tray saturated with 0.01% benzocaine solution. The foam lining kept the salamander's skin moist and prevented the animal from sliding during surgery. To keep the

skin moist and ensure continued anesthetization, several pieces of anesthetic-soaked cotton gauze were placed over the animal's body so that only the flank was exposed.

An 8–10 mm incision was made mid-laterally in the left flank to reduce the incision site's contact with substrate or moving limbs during normal locomotion while healing. To initiate the incision, a pinch of skin was raised with forceps from underlying muscle and cut cranio-caudally with sharp-tipped scissors. A small hole was then punctured through the muscle and peritoneal membrane using the tips of the closed scissors and widened by opening the scissors slightly. Lifting the muscle with forceps, we extended the incision with scissors, being careful to avoid any internal organs. Sterile cotton applicators were used to absorb fluid from the body cavity or to apply pressure to bleeding vessels.

Each transmitter was dipped in molten paraffin 3 times prior to implantation to create an inert surface and to reduce the possibility of an inflammatory response. Then each transmitter was soaked for 24 h in a 5% Chlorhexidine solution (Novisan, Fort Dodge) to ensure sterility, rinsed in sterile saline solution to remove the disinfectant, and placed within the coelomic cavity (parallel to the spine) with battery oriented anteriorly and helicoil antenna dorsally.

The muscle was closed by continuous suture of 4-O or 5-O polyglactin 910 (Vicryl, Ethicon) with a taper needle; suture material was soaked in 12.9% Benzalkonium chloride (Benz-all, Xttrium Laboratories) for ca. 24 h before surgery (to soften the thread) and rinsed in saline at time of use. The skin was closed using approximately 3 horizontal mattress sutures (ca. 2 mm wide and 2 mm apart) of 4-0 or 5-0 polyglactin 910 with a cutting needle. Skin sutures were not drawn as tightly as those in muscle tissue to prevent necrosis. The closed incision site was wiped clean with gauze. Mean surgery time per individual was 21 minutes.

While nonabsorbable 4-O silk suture material has been recommended because of its cost and handling characteristics (Boothe 1985), our earlier experiments with silk suture material resulted in severe fungal infection in *D. tenebrosus* unable to shed the sutures. Silk suture material causes greater tissue reaction (Boothe 1985) and a higher frequency of infection (Sugarman and Musher 1981) than nylon suture material. We used absorbable Polyglactin 910 sutures and found them to be compatible with larval salamanders.

To resuscitate animals, recovering individuals were placed in a 5-gallon bucket of cold spring water and the water was stirred and changed frequently to increase the exchange of oxygen and dilution of the anesthetic. Recovery time averaged 27 minutes and the total procedure (anesthesia, surgery, recovery) time per individual averaged 62 minutes.

Salamanders were then held in tubs for 10–20 days to monitor their behavior and to assure that the sutures remained intact; failing sutures were replaced immediately as described above. At the time of release, we remeasured weight and snout-vent length, documented incision status, and applied malachite green, an anti-fungal agent, to the incision site.

During June and July, 1995, nine of the salamanders were translocated to the upper Sacramento River and ten were released at their points of capture. Fourteen salamanders were recaptured between September and mid-October, 1995. Incisions in 8 of the 14 recaptured salamanders were completely healed (4 each from tributaries and river), 4 were partially healed (3 from tributaries and one from river), and two were not healed (both from tributaries). Incision healing time may be affected by water temperature. Higher metabolic rates and faster healing times are associated with higher temperatures in fish (Anderson and Roberts 1975) and snakes (Smith et al. 1988); larval *Dicamptodon* body temperatures are the same as the water temperature (Brattstrom 1963) and their metabolic and healing rates are assumed to increase with increasing water temperatures.

Our observations of individuals radiotracked for a few weeks during 1994–1995 indicate that these salamanders remain fairly sedentary in winter when water temperatures are colder. One individual, implanted with a transmitter in October, 1994, and maintained in cold spring water in the lab, took six months to heal. While healing time may have been influenced by the suture material (silk), it may also have been increased by cold water temperature and the animal's inactivity during winter. Most incisions healed within three months during summer. Individuals implanted with transmitters in the summer were more active, and the water temperature was also generally warmer; we recommend timing implant surgery for aquatic salamanders to correspond with the organism's most active season. Maintaining or releasing animals in waters at the higher end of the salamander's preferred temperature range may accelerate healing.

Acknowledgments.—We thank Kelly Kawsuniak for assistance with the surgery and Patrick Hendrix, Leslie Hubbard, Kelly Kawsuniak, Christine Sousa, and Vincent Whitman for assistance with the field work. Bruce Deuel, Mark Stopher, and Angela Stringer made editorial comments on earlier drafts of this manuscript. This study was supported by the California Department of Fish and Game as part of the Cantara Spill Natural Resource Damage Assessment.

A New Trap for the Live Capture of Large Lizards

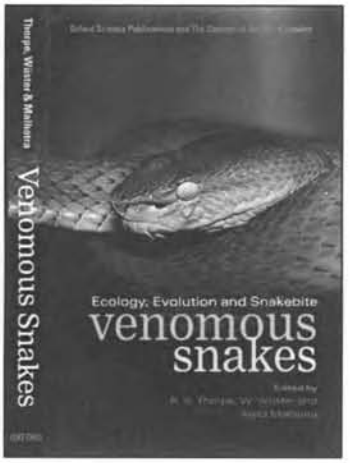
TIFFANY M. DOAN
Department of Biology, University of South Florida
Tampa, Florida 33620, USA
e-mail: doan@chuma.cas.usf.edu

Large, wide-ranging lizards are often difficult to catch (Auffenberg 1978). Drift fence-pitfall trapping, the use of rubber bands, and noosing (Simmons 1987) may be ineffective for large lizards.

In a recent investigation (Doan, unpubl.), *Tupinambis teguixin* home range was studied in remote Peruvian rainforest. Although large wire mesh traps (e.g., Havahart™ and Tomahawk™) may be used to catch large lizards (King et al. 1994), it was not possible for me to transport large traps to the field. H. B. Sherman Traps, Inc. (P.O. Box 20267, Tallahassee, Florida 32316, USA; tel. 904-575-8727) constructed collapsible aluminum traps similar to Sherman™ mammal traps but composed of solid aluminum on three sides and expanded metal on one side (for viewing the contents of a closed trap), that measure 88.5 cm x 31.0 cm x 31.0 cm when in use and collapse to 88.5 cm x 31.0 cm x 5.0 cm for transport.

In the field I camouflaged the traps by laying green mosquito netting over the trap, tucking it underneath. Fallen branches and leaves were placed on top of the trap and inside on the spring door. I tried live and dead rats, hen eggs, canned cat food, and bananas as bait, but all captures of *T. teguixin* were made in traps baited with hen eggs. Cracked eggs were placed in wire mesh suspended in the back of the trap. When camouflaged and baited appropriately, this new trap was successful in capturing *T. teguixin* and did not appear to influence the possibility of recapture.

These new, collapsible Sherman traps are easy to transport and effective for catching large lizards. Incidental captures during my study included *Ameiva ameiva*, *Didelphis marsupialis* (common opossum), *Sylvilagus brasiliensis* (Brazilian rabbit), and *Proechimys* spp. (spiny rats). The mammals were captured with various bait types, demonstrating the potential of the new trap for studies where larger animals are sought and trap portability is important.



Acknowledgments.—I thank G. Phillips of H. B. Sherman Traps, Inc. for designing, building, and shipping the traps; without his help this study would not have been possible. I also thank C. Galvez-Durand and P. van Ipenburg for battling Peruvian customs to retrieve the traps, and H. Mushinsky for guidance and support.

***Author to whom all correspondence should be addressed.*

Maternal brooding of salamander embryos has been shown to increase embryonic survival (Forester 1979; Harris et al. 1995; Salthe and Mecham 1974; Tilley 1972). However, a variety of different experimental protocols require that eggs be isolated from the brooding female. Experimental designs involving quantitative genetics (Falconer 1989) and kin discrimination (Waldman 1991) involve separating eggs from each female into groups of various sizes for rearing in order to remove the effect of "female brooding" from an experiment. In addition, it is impossible for one female to brood more than one isolated cluster of her eggs. Unfortunately, previous attempts at artificial brooding of salamander eggs have met with limited success. Forester (1979) removed brooding *Desmognathus ochrophaeus* and used an artificial brooding technique in the laboratory that yielded more than 90% mortality due to fungal infection within 28 days. In an attempt to increase the survival of four-toed salamander embryos, *Hemidactylium scutatum* (Caudata: Plethodontidae), in the absence of the brooder, we developed a novel method of artificial brooding.

Eggs were placed into 6 x 8 x 4 cm hard plastic containers containing a single layer of filter paper dampened with artificial pond water (modified Provosoli medium, no vitamins, not autoclaved: Wyngaard and Chinnappa 1982). All containers were covered with a hard plastic lid and coated with Parafilm to prevent desiccation of the eggs. Young embryos were maintained on a 24:0 h (light:dark) photoperiod at 16°C. This photoperiod was convenient for us because it allowed animal care to be scheduled at any time. When the neuromuscular system began to function, embryos were placed on a 14.5:9.5 h photoperiod at 18°C to mimic natural conditions. Container arrangements were systematically changed within the incubators to eliminate effects of temperature and light gradients.

Containers were checked under the dissecting scope to assess developmental stage and to check for fungus. Any infected eggs were teased away from the cluster and removed to reduce the likelihood of infection of the other eggs. All viable eggs were cleaned as follows. Eggs in their container were rinsed with a squirt jar containing artificial pond water (modified Provosoli medium), removed with a plastic spoon, and placed in a petri dish to be rinsed again. While the eggs were out of the container, the containers were rinsed and swabbed with 70% EtOH and rinsed five times with hot tap water. Fresh filter paper was placed in the container. The eggs were then spooned out of the petri dish, rinsed a third time while in the spoon, and placed gently on the fresh dampened filter paper. The petri dish and the plastic spoon were sterilized with 70% EtOH after each use. Containers were cleaned daily during the first third of the embryonic period, every third day in the second third of the embryonic period, and every seventh day in the last third of the embryonic period. As the embryos approached hatching, the cleaning scheme was modified to avoid premature hatching. The embryos were rinsed in their container with a squirt jar containing modified Provosoli and rolled daily. Eighty-two percent of the embryos survived 4–6 weeks to hatching (467 eggs hatched out of 570). We have had less experience raising eggs of *D. ochrophaeus* and *D. monticola* from the earliest embryonic stages with this method, but results obtained were comparable to those obtained for *H. scutatum*.

Acknowledgments.—We thank Carrie Carreno for help with raising embryos. This research was supported by National Science Foundation grant DEB 92-07186 to Reid N. Harris and Ivor T. Knight.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 28, Number 1 (March 1997).

CAUDATA

AMBYSTOMA TIGRINUM MELANOSTICTUM (Blotched Tiger Salamander). **PREDATION**. Predators of salamanders in the Pacific Northwest are poorly known. Leonard et al. (1993. Amphibians of Washington and Oregon. Seattle Audubon Soc., Seattle. viii + 168 pp.) reported that aquatic salamanders may be eaten by other salamanders, garter snakes, and certain species of mammals and birds. On 13 March 1996 at ca. 1500 h PST, a mink (*Mustela vison*) was observed on the shore of a small pond adjacent to a second pond that is a known breeding site for *Ambystoma tigrinum melanostictum, A. macrodactylum columbianum,* and *Pseudacris regilla*. Both ponds are located on the south edge of the Washington State University campus in Pullman. Several minutes after diving into the water the mink reappeared, carrying a branchiate tiger salamander ca. 175–200 mm TL. The mink then disappeared into a den behind some small boulders carrying the salamander.

Submitted by **JULIE A. FRONZUTO**, Department of Zoology, Washington State University, Pullman, Washington 99164-4236, USA.

ANEIDES LUGUBRIS (Arboreal Salamander). **PREDATION.** There are few published records of predation on terrestrial salamanders. Antipredator defense mechanisms (e.g., noxious skin secretions, tail undulation), in addition to nocturnal, secretive habits, serve to protect these species from potential predator encounters (Brodie 1983. *In* N. S. Margaris, M. Arianoutsou-Faraggitaki, and R. J. Reiter (eds.), Plant, Animal, and Microbial Adaptations to Terrestrial Environments, pp. 109–133. Plenum Publ. Corp., New York). Herein we report the predation of an adult *Aneides lugubris* by a southern Pacific rattlesnake (*Crotalus viridis helleri*).

On 12 May 1975 at 0745 h a *C. v. helleri* (325 mm SVL, 19.5 g) was collected in Carroll Canyon on Carroll Canyon Rd, 0.6 km S El Camino Memorial Park, San Diego County, California, USA (T15S R3W NW1/4 Sec 10; 65 m elev.). The hillside vegetation was dominated by coast live oak (*Quercus agrifolia*). The rattlesnake was brought to the laboratory, caged, and on the following day a partially digested *A. lugubris* (81 mm SVL, 9.1 g) was found regurgitated. It appeared that the salamander was swallowed head first. It is not known if the salamander was active on the surface when encountered, or if regurgitation was the result of noxious skin secretions. This is the first published record of predation of *A. lugubris* by a snake.

The only previous record of predation is by the California scrub jay (*Aphelocoma coerulescens*) (Rubinoff 1996. Herpetol. Rev. 27:135). Colubrid snakes (*Diadophis punctatus, Contia tenuis, Thamnophis* spp.), frogs (*Rana aurora, R. catesbeiana*), and Jerusalem crickets (*Stenopelmatus* spp.) are known to eat *Ensatina* and *Batrachoseps* (Stebbins 1954. Univ. California Publ. Zool. 54:47–124), plethodontid salamanders sympatric with *A. lugubris*. Mahrdt (unpubl. field notes) observed an adult *Diadophis punctatus* from La Mission, Baja California Norte, México regurgitate a juvenile *A. lugubris* in March 1975.

We thank Steven P. Sandberg for collecting the specimen and Kent R. Beaman for commenting on the manuscript. A photograph of the *A. lugubris* was deposited at the San Diego Museum of Natural History.

Submitted by **CLARK R. MAHRDT** and **BENJAMIN H. BANTA**, Southwest Biological Associates, 9847 Willow Lane, Escondido, California 92029, USA.

BATRACHOSEPS ATTENUATUS (California Slender Salamander). **PREDATION.** On 2 April 1996 at ca. 0800 h I observed a California shrub jay (*Aphelocoma coerulescens*) predate the tail of a 50 mm SVL *Batrachoseps attenuatus*. The sky was clear, temperature was ca. 30°C, and it had rained the previous night. Predation occurred on Stanford University campus on a live oak-lined sidewalk bordered by mown grass and a parking lot. The shrub jay seized the salamander by the tail, which promptly abscised, and proceeded to swallow the wriggling appendage without further processing. The salamander continued ca. 7 m down the sidewalk to the observer where it was picked up, examined, and measured. Jaeger (1981. Am. Nat. 117:835–837) regarded birds as being inefficient predators on terrestrial salamanders. His conclusions were based on evidence that birds avoid feeding on aposematic species and their mimics (Brodie and Brodie 1979. Science 208:181–182), and that forest birds are most efficient at catching salamanders in dry periods when the prey items are scarce. Rubinoff (Herpetol. Rev. 27:135) observed predation by *A. coerulescens* on a diurnally active *Aneides lugubris*. It is possible that such events are only uncommon due to temporal separation in predator-prey activity cycles; *A. coerulescens* is diurnal and all salamanders in the region are typically nocturnal. *Aphelocoma coerulescens* are often abundant where they occur, aggressive, and opportunistic. Urban populations of the species are increasing, particularly in winter months (Marzluff et al. 1994. Stud. Avian Biol. 15:202–220) when many amphibians are breeding and most actively foraging. Predation by this avian species may place significant pressure on co-occurring amphibian populations and explain, in part, why so many amphibians in this region are active at night even in the winter when moisture is not a nocturnally-defined resource.

Submitted by **JAMIE KRISTINE REASER**, Center for Conservation Biology, Department of Biological Sciences, Stanford University, Stanford, California 94305 USA.

DESMOGNATHUS MONTICOLA (Seal Salamander). **OOPHAGY**. As part of a study of oviposition in *Desmognathus monticola* in Banks County in the Georgia Piedmont (USA) during 1995, I measured females that were attending clutches and counted their eggs. As the favored nesting site was horizontal crevices in wet cliffs, I captured each female by enticing her out with bait (Camp and Lovell 1989. Herpetol. Rev. 20:47). On 17 August 1995 I removed a 65 mm SVL female associated with a clutch of 14 eggs from a crevice that she shared with at least two other females attending clutches, as well as several males and non-attending females. Upon attempting to return her ca. 15 min later, I noted only 3 of her eggs remained, and an adult conspecific had its head among the remains of the clutch. I collected and preserved this specimen, a 67 mm SVL adult female with ova in an intermediate state of development. Dissection revealed the missing 11 eggs (mean diameter = 4.8 mm) in her stomach and esophagus. This is the first report of conspecific oophagy in this species, al-

though it has been reported for *D. ochrophaeus* and *D. fuscus* (Polis and Myers 1985. J. Herpetol. 19:99–107). This report also emphasizes the importance of attending female *Desmognathus* in protecting clutches from predation (Forester 1988. J. Herpetol. 12:537–541). The specimen will be deposited in the University of Georgia Museum of Natural History.

Submitted by **CARLOS D. CAMP**, Department of Biology, Piedmont College, Demorest, Georgia 30535, USA.

EURYCEA QUADRIDIGITATA (Dwarf Salamander). **COLORATION**. On 20 March 1995, I captured a xanthic *Eurycea quadridigitata* larva, along with numerous normally pigmented larvae, in a 1.5 ha pond cypress (*Taxodium ascendens*) swamp on Cecil Field Naval Air Station, Duval County, Florida, USA. In life, the dorsum and eyes of the larva were golden yellow, the venter translucent pink, the gills pink (due to presence of erythrocytes), and the anterior and posterior margins of each orbit bordered by patches of melanin. The larva was maintained in captivity through metamorphosis (21 mm SVL), then preserved in the vertebrate collections at Southern Illinois University at Carbondale (SIUC H-5193). To my knowledge, this is the second report of an abnormally pigmented *Eurycea quadridigitata* (Dyrkacz 1981. SSAR Herp. Circ. 11. 31 pp.).

This larva was collected while conducting amphibian surveys for the Jackson, Mississippi office of the U.S. Fish and Wildlife Service. I thank L. V. LaClaire for funding and R. A. Brandon for loaning me the Dyrkacz reference.

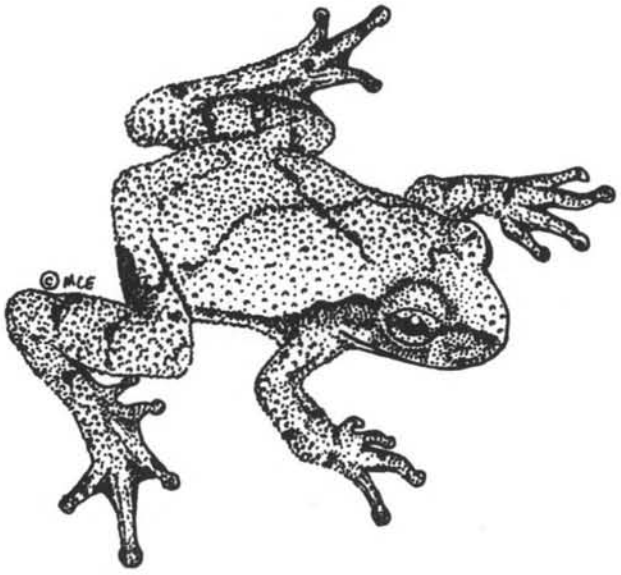
Submitted by **JOHN G. PALIS**, 529 North Main Street, Jonesboro, Illinois 62952, USA.

GYRINOPHILUS PORPHYRITICUS PORPHYRITICUS (Northern Spring Salamander). **PREY.** Many amphibians secrete noxious or toxic substances from their skin rendering them unpalatable to some predators. Among these is the red eft, the terrestrial juvenile stage of *Notophthalmus viridescens viridescens*, which produces neurotoxic tetrodotoxin (Duellman and Trueb 1994. Biology of Amphibians. McGraw-Hill Book Co., New York. xvii + 670 pp.; Wakely et al. 1966. Toxicon 3:195–203). We report predation upon a red eft by *Gyrinophilus p. porphyriticus*.

Gyrinophilus p. porphyriticus is typically found in cool springs, mountain streams, or in wet areas under rocks and logs (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin, Boston, Massachusetts, 450 pp.), but are known to wander large distances to more terrestrial habitats (Dunn 1926. The Salamanders of the Family Plethodontidae. Smith College, North Hampton, Massachusetts, 441 pp.; J. Secki and A. Queral-Regil, pers. obs.). This salamander is characteristically active and aggressive (Dunn 1926, *op. cit.*). Previous reports on the stomach contents of *G. p. porphyriticus* include earthworms, snails, spiders, fly larvae, ground beetles, millipedes, and crustacea (Smith 1913 *in* Dunn 1926, *op. cit.*). Predation by *G. p. porphyriticus* on salamanders (*Hemidactylium scutatum, Eurycea bislineata* and their larvae, *Desmognathus fuscus* and their larvae), a young wood frog (*Rana sylvatica*), and two larvae of its own species has also been reported (Wright and Haber 1922 *in* Dunn 1926, *op. cit.*). To our knowledge, there are no published accounts of predation upon *N. viridescens* by *G. porphyriticus*.

On 12 June 1995 at ca. 2200 h, we captured a female *G. p. porphyriticus* (110 mm SVL, 66.6 mm TL, 17.9 g) at Mountain Lake Biological Station, Giles County, Virginia, USA. During handling for measurements the following morning, the salamander regurgitated a red eft (20.43 mm SVL, 19.10 mm tail length). The red eft was partially digested but the characteristic red spots were distinguishable, making identification certain.

Studies of *N. v. viridescens* suggest that its toxicity is related to individual size of the eft (Brodie et al. 1974. Copeia 1974:506–511), which may explain the lack of ill effects on the spring salamander. Alternatively, some *G. p. porphyriticus* may not be affected by the neurotoxin produced by *N. v. viridescens*. Tetrodotoxin tolerance has apparently arisen in other predators of newts (Brodie and Brodie 1990. Evolution 44:651–659). *Notophthalmus v. viridescens* is known to be eaten by *Thamnophis sirtalis*, shrews (*Sorex* spp.), and some birds (E. D. Brodie, III, pers. comm.). Our observations suggest that tetrodotoxin tolerance may be more widespread among terrestrial predators than previously thought.



We thank R. B. King and E. D. Brodie, III for assistance with earlier drafts of this report.

Submitted by **JENNIFER A. SECKI**, Department of Biology and Mountain Lake Biological Station, University of Virginia, Charlottesville, Virginia 22903, USA, and **ALEJANDRO QUERAL-REGIL**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA.

TARICHA GRANULOSA (Roughskin Newt). **TOXICITY.** Three dead fledgling pied-billed grebes (*Podilymbus podiceps*) were discovered between 31 July and 7 August, 1996 floating on the surface of a pond in Pacific County, Washington, USA, along the North River 3.5 km E of Brooklyn. As each was discovered, it was retrieved and frozen. During necropsy a single, partially digested *T. granulosa* was found in each bird's stomach. A pathologic examination revealed severe pulmonary congestion and edema with no other gross or microscopic pathological findings. The grebes appeared in good condition and no parasites were noted. Brodie (Copeia 1968:307–311) demonstrated the susceptibility of birds to *Taricha* skin toxin in a laboratory environment. Isolation and identification of small amounts of tetrodotoxin is currently not practicable and E. D. Brodie, Jr. (pers. comm.) expected little toxin to be present in tissue samples. Brodie further commented that a grebe having eaten a newt would die within minutes, even before the newt was dead. Our observations strongly suggest mortality of wild pied-billed grebes due to ingestion of *T. granulosa*. One of the recovered *T. granulosa* was deposited in the University of Texas at Arlington Collection of Vertebrates (A-48993).

TARICHA TOROSA (California Newt). **RESPONSE TO FIRE.** On 10 April 1996, a prescribed burn was ignited on a steep, south-facing hillside dominated by chamise (*Adenostoma fasiculatum*) on the Hastings Natural History Reservation, Carmel Valley, Monterey Co., California, USA. Scattered coast live oaks (*Quercus agrifolia*) grow along the lower reaches of this hillside. One large live oak on a SW exposure had an accumulation of 10–20 cm of leaves below the canopy that likely offered dry-season refugia for newts. This litter was ignited at ca. 1400 h and was still

burning at 1700 h when attempts were made to extinguish the flames, which were 5–10 cm high and moving ca. 1–5 cm/min. I noticed a pair of *Taricha torosa* moving over the unburned litter. They both appeared very shiny and wet and were moving rapidly (ca. 5 cm/sec). Each newt walked directly into the flame front and did not pause while walking through the burning leaves. The slime covering their bodies foamed up, resembling an egg meringue. Within 20–30 s they were through the flames and on the cool, black ashes of the litter. Upon close examination, the now crusty white coating easily wiped off their wet bodies. I did not observe any skin blisters and the skin color looked normal. The newts were returned to the forest litter and they continued to walk downhill. They did not stop or curl up but walked normally, proceeding at near-record newt speed. As they walked through patches of unburned grass, the leaves and litter removed almost all of the thin, white crust. They walked under a rotting log in dense litter and I did not follow them further.

Fires are frequent in central, coastal California where *T. torosa* is common. Foaming of the skin secretions would dissipate heat and may be a mechanism used by this species to escape wildland fires.

Submitted by **MARK R. STROMBERG**, Hastings Natural History Reservation, University of California, Berkeley, 38601 East Carmel Valley Road, Carmel Valley, California 93924, USA.

ANURA

BUFO AMERICANUS (American Toad). **REPRODUCTION**. In many anuran species with a male-biased operational sex ratio, alternative male mating strategies have been reported (Arak 1983. *In*. P. Bateson (ed.), Mate Choice. Cambridge Univ. Press, Cambridge,. 462 pp.). For prolonged breeders, such as *Rana catesbeiana*, satellite males have been described (Howard 1978. Evolution 32:850–871) and Arak (*op. cit.*) found that small males of the explosive breeders *Bufo bufo* and *R. temporaria* searched for females away from the communal spawn site. Here I report a new alternative mating behavior in the explosive breeder *B. americanus*.

FIG. 1. Small male *Bufo americanus* in contact with an amplectant pair.

This behavior was observed in Lincoln Pond on the E.N. Huyck Preserve, Rensselaerville, New York, USA (42°10'N, 74°10'W; ca. 550 m elev.). At 1700 h on 4 June 1996, two small males were seen in separate incidences sitting with their cloacal region against the cloacal region of females that were in amplexus with larger males (Fig. 1). During 10 min of observation, the small males called repeatedly and maintained contact with the females even when the amplectant pairs were moving. This form of matesneaking may be an alternative for males that have a low probability of winning contests against other males due to their smaller body size, since size-dependent mating has been described for *B. americanus* when male density is high (Gatz 1981. Anim. Behav. 29:1004–1012.).

This observation was made during research funded by a grant from the E.N. Huyck Preserve, Rensselaerville, New York. I am thankful for the opportunity to do research at this site. I thank Margaret Stewart and Jennifer Frank for reviewing this manuscript.

Submitted by **STEFAN K. KAMINSKY**, Department of Biology, State University of New York, Albany, New York 12222, USA.

HYLA CREPITANS (NCN). **PREDATION**. On 6 May 1992, at a small permanent pool 13 km (by road) S of Las Bocas village, going to Pueblo Nuevo de la Sierra, Municipio Colina, Estado Falón, north-midwestern Venezuela, 245 m elev., one of us (JMH) observed a giant water bug (total length 61.6 mm) (Belostomatidae, *Belostoma* sp.) that had captured an adult male *Hyla crepitans* (SVL 57.2 rnm) by its hindlimbs. The frog had a small wound near the anal opening on the posterior surface of the hind limb. When collected the frog was very weak and could not move its hindlimbs; it later died. The specimen is deposited in the Regional Collection of Reference, Centro de Investigaciones en Ecologia y Zonas Aridas (CIEZAH 321), Universidad Francisco de Miranda, Coro, Venezuela.

Although we did not observe the capture, we suspect that predation by giant water bugs is related to the frog's habit of calling on the surface of the water, thus attracting the attention of the predator as reported for other hylid frogs including *Hyla versicolor* and *Pseudacris crucifer* (Hindshaw and Sullivan 1990. J. Herpetol. 24:196–197).

Submitted by **ABRAHAM MIJARES-URRUTIA, ALEXIS ARENDS**, Centro de Investigaciones en Ecología y Zonas Aridas (CIEZA), Universidad Francisco de Miranda, Coro, Venezuela, and **JEAN-MARC HERO**, Department of Zoology, James Cook University, Townsville, Queensland 481 1, Australia.

LEPTODACTYLUS PENTADACTYLUS (Rana Ternero, Smoky Frog). **PREDATION**. Anurans possess a number of defense mechanisms that discourage predators, but the effectiveness of these mechanisms is rarely observed in the field. *Leptodactylus pentadactylus*, a large frog of Central America, emits loud shrieks when caught (Villa 1969. Rev. Biol. Trop. 15:323–329) perhaps to startle a mammalian predator into dropping it, or to attract caiman, which might prey on the predator, thus freeing the frog (Scott 1983. *In* D. H. Janzen (ed.), Costa Rican Natural History, pp. 405–406. Univ. Chicago Press, Chicago, Illinois). *Leptodactylus pentadactylus* also secretes leptodactylin, a neuromuscular block and a nervous system stimulant (Scott and Limerick 1983, *In* D. H. Janzen (ed.), Costa Rican Natural History, pp. 351–367. Univ. Chicago Press, Chicago, Illinois), which might deter predation. On 14 June 1992 I heard grunts from a southern river otter (*Lutra*

longicaudis) and found it digging deep under a *Pentaclethra macroloba* tree on the edge of the Research Swamp at the La Selva Biological Station, 32 m elev., Heredia Province, Costa Rica. I watched the otter from a distance of 3 m as it dug into a burrow of *L. pentadactylus*. At night I had frequently observed an adult *L. pentadactylus* just outside this burrow. At 1053 h I heard the loud squeal emitted by *L. pentadactylus* when seized by a predator. The otter rapidly swam out from under roots on the far side of the tree holding in its paws an adult *L. pentadactylus* with only one hindleg. The otter stuffed the frog into its mouth and severed the remaining leg at the body, it then appeared startled by my presence and swam to the far side of the tree where I could not see it. I heard loud crunching sounds for ca. 3 s after which the otter swam back into view. It was not holding the frog and I did not see the *L. pentadactylus* again, nor was it present outside its burrow that evening. I assumed the river otter had completely consumed the frog. I could detect no startle response by the otter when the frog screamed, nor any reaction by the otter to noxious skin secretions. After at least 10 min of vigorous digging to extract the frog from its burrow, the otter consumed the frog completely in less than 30 s.

Submitted by **WENDY E. ROBERTS**, Mountain Research Center, 408 Traphagen Hall, Montana State University, Bozeman, Montana 597173490, USA.

LYSAPSUS LIMELLUS (NCN). **PARASITISM.** *Lysapsus limellus* is restricted to the areas adjacent to the Paraguay and Parana rivers, from Rondonia and Matto Grosso (Brazil) to central Argentina. In Argentina *L. limellus* occurs in the provinces of Formosa, Chaco, Corrientes, Santa Fe, and north of Buenos Aires (Cei 1980. Amphibians of Argentina. Monit. Zool. Ital. (NS) Monog. 2:609 pp). They are extremely aquatic, occurring in semipermanent and permanent ponds. On 23 May 1994, as part of an investigation of the trematode guild structure in a natural population of *L. limellus,* we collected 14 frogs; 8 females (SVL 14–20 mm; mean 16.25; SD = 1.98) and 6 males (SVL 11–19 mm; mean = 15.67; SD = 1.98). These specimens were collected in a permanent pond 15 km NE of Corrientes Capital (27°28'S, 58°50'W), province of Corrientes, Argentina. Thirteen frogs (93%) were infected by trematodes: 1) adult parasites, *Catadiscus* aff. *propinquus* Freitas and Dobin 1956 localized in the large intestine, prevalence was 64%, intensities ranged from 1–13 (mean = 4.6, SD = 3.8/host, N = 41); and *Glypthelmis* aff. *vitellinophilum* Dobin 1958 localized in the small intestine, prevalence was 36%, intensities ranged from 1–12 (mean = 4.2, SD = 4.5/host, N = 21); 2) larval stages (metacercariae) Diplostomidae (aff. *Lophosicyadiplostomum* Dubois 1936), 1 localized in the kidney, prevalence was 57%, intensities ranged from 2–50 (mean = 31.3, SD = 16.2/host, N = 250); and Echinostomatidae (species 1), localized in the lung, prevalence was 21%, intensities ranged from 5–10 (mean = 6.7, SD = 2.9/host, N = 20). In general, the prevalence and mean intensity by trematodes was high. This high incidence of infection could be related to: 1) the type of host diet, 2) the abundance of definitive and intemmediate hosts, and 3) the limnological features of the habitat. The importance of the biotic or abiotic factors influencing the parasite community organization in amphibians has been reviewed by Aho (1990. *In* G. W. Esch, A. O. Bush, and J. M Aho (eds.), Parasite Communities: Pattems and Processes, pp. 157–195. Chapman and Hall, New York). It is likely that *L. limellus* is the principal intemmediate host for metacercariae Diplostomidae, considering the prevalence and intensity of these trematodes in most of the frogs we collected.

Submitted by **MONIKA I. HAMANN** and **ARTURO I. KEHR**, Centro de Ecologia Aplicada del Litoral, C.C. 140, (3400) Corrientes, Argentina.

RANA AURORA DRAYTONII (California Red-legged Frog). **BEHAVIOR.** This frog was recently listed by the U.S. Fish and Wildlife Service as Threatened (Fed. Reg. 23 May 1996. 61(101):25813–25833). Organizations wanting to create or modify wetlands may need to control movements of frogs to reduce incidental mortality during construction, or to prevent breeding attempts in unsuitable habitats. The Cambria Community Services District, in anticipation of federal protection, wanted to prevent red-legged frogs from breeding in four newly constructed sewage percolation ponds adjacent to San Simeon and Van Gordon creeks, San Luis Obispo County, California, USA. To exclude frogs, the District attached a 1.2 m high plastic barrier (Tensar Polygrid Windbreak) to the outside of a 1.8 m high chain-link fence surrounding the 6.8 ha compound during the summer of 1995.

In January 1996, two radio-tagged frogs (Rathbun and Murphey 1996. Herpetol. Rev. 27:187–189) that we had been following outside the compound near Van Gordon Creek appeared in the only percolation pond with water. During a night survey of the pond on 14 March, we saw or heard at least 10 adult frogs, and captured two calling males (No. 1, 94 g, 99 mm SUL [snout-urostyle length] and No. 2, 84.5 g, 95 mm SUL). We found three gaps in the frog barrier at ground level (associated with gates and pipes entering the compound) where the frogs could have entered; they also could have climbed or jumped over the barrier.

To determine if frogs could pass over the barrier, we designed a simple test. We built a three-sided plywood enclosure on the outside of the Tensar/chain-link fence, ca. 20 m from the watered percolation pond. The walls were buried ca. 15 cm and were ca. 1 m high. The enclosure was tightly attached to the fence so that there were no gaps, and the top was covered with one-inch mesh (2.5 cm) chicken wire to exclude predators. We left a gap between the chicken wire and the Tensar barrier of 45 cm; if the frogs made it to the top of the barrier they could easily go through the chain-link fence into the compound. The vegetation was cleared from the inside of the test enclosure, water dishes were provided, and cement construction blocks were put in for cover.

On 18 March at ca. 1500 h, we radio-tagged frog Nos. 1 and 2 and introduced them into the enclosure. We observed them for ca. 5 h. During this time, they jumped and clung to the barrier, but they did not get higher than ca. 30 cm. When we checked on 19 March at 1730 h, we found frog No. 1 in the watered percolation pond. On the night of 18 March we captured, radio-tagged, and released two adult females in the pond (No. 3, 167 g, 119 mm SUL and No. 4, 144 g, 113 mm SUL). In addition, we caught another male (No. 5, 99 g, 100 mm SUL); he was radio-tagged and released into the test enclosure on 20 March at 1200 h. At 1000 h on 21 March, frog No. 2 was back in the percolation pond, and at 1000 h the next day frog No. 5 was found in the pond. The three male frogs passed over the frog barrier within three days.

For operational reasons, the percolation pond was drained between 16–28 April 1996, when frog Nos. 1–5 were present. On 24 April we found the damaged radio of frog No. 1 at the base of the fence, inside the compound, suggesting that he was eaten by a predator. Radio contact with frog No. 2 was lost on 27 April. Frogs 3 and 5 were found dead and desiccated at the base of the fence on the inside of the compound on 2 May and 26 April. Female frog No. 4 left the pond on 24 April and was found outside the compound, near Van Gordon Creek, on 27 April.

We do not know whether the frogs that entered or left the compound passed through the ground-level gaps in the barrier or passed over it; our experiment demonstrated that they are able to climb or jump the Tensar/chain-link barrier from the outside. Based on frog mortality we documented, it is possible that *R. a. draytonii* was unable to climb the Tensar/chain-link barrier from the inside. Our experiment demonstrates the necessity of designing, testing, and installing barriers carefully, and the possibility that barriers may cause mortality.

We thank the Cambria Community Services District, San Simeon State Park, and California Department of Transportation for their support and cooperation. Brian Hatfield, Dan Holland, and Mark Jennings reviewed early drafts of the manuscript. This work was done under Permit No. 9593 from the California Department of Game and Fish.

RANA PRETIOSA (Spotted Frog). **PREDATION**. During climax metamorphosis anurans can neither swim as well as a tadpole nor leap as well as a frog, and are at increased risk of predation (Wassersug and Sperry 1977. Ecology 58:830–839; Arnold and Wassersug 1978. Ecology 59:1014–1022), yet predators actively foraging on transforming frogs are rarely observed in the field. On 6 August 1996 I watched three northern river otters (*Lutra canadensis*) feed on metamorphosing *Rana pretiosa* at Buck Lake, 2116 m elev. in the Northern Range of Yellowstone National Park, Park Co., Wyoming, USA. From 1621–1626 h the otters (one adult and two large juveniles) caught and consumed three transforming frogs. I observed the otters feeding on a rock ca. 10 m from shore. They caught the transforming frogs in the water within an 8 m radius of the rock, and returned to the rock to consume the frogs. Each metamorphosing frog had a long complete tail, hindlegs, and in one case forelegs; I estimated they were Gosner stages 41 or 42 (Gosner 1960, Herpetologica 16:183–190). The length of the transforming frogs was ca. 6–7 cm from snout to tip of tail; the only frogs of that size inhabiting alpine ponds of Yellowstone National Park are *R. pretiosa* (Koch and Peterson 1995. Amphibians and Reptiles of Yellowstone and Grand Teton National Parks, Univ. Utah Press, Salt Lake City. 188 pp.). After five minutes of feeding the otters stopped foraging and swam to another part of the lake. I searched the lake shore and found two otter latrines, one fresh and one several days old. The scat was black and mushy, and did not contain identifiable food items, neither fish bones nor the crayfish parts I have seen in otter scat. The lack of identifiable hard fish or crustacean components in their scat suggests the river otters may have been feeding exclusively on transforming frogs for several days. The partly ossified bones of metamorphosing frogs may not be apparent in scat.

RANA PRETIOSA (Spotted Frog). **BEHAVIOR and REPRODUCTION**. On 2 February 1996, we (WPL and LAH) observed three *R. pretiosa* beneath a 5-6 cm layer of translucent ice completely covering a seasonal pond in a grazed pasture adjacent to Dempsey Creek, Thurston County, Washington, USA (T17N R3W Sec. 13) at 43 m elevation. We observed a gravid female swim a distance of 5 cm and nuzzle the bottom. We found a second female under the ice less than 2 m from the first frog. We presumed it dead because it was motionless and floating upside-down. When we removed it from beneath the ice, a male fell from its back, suggesting a pair in amplexus. All three individuals moved sluggishly when removed from the frigid (-0.5°C), shallow (9-14 cm) water. We (WPL and KRM) returned to the site at 1106 h on 4 February and observed another male *R. pretiosa* swimming beneath the ice for a distance of 0.5 m. The water temperature was 1.0°C. All four individuals were in breeding condition as evidenced by the prominent nuptial pads on the males' thumbs and the obviously distended abdomens of the females. These individuals were found in the same location where we (WPL and KRM) found 41 *R. pretiosa* egg masses between 23 February and 12 March 1995.

All surface water in the vicinity of the breeding pool is seasonal, drying in the early summer and refilling in the late fall. During the summer months *R. pretiosa* are found in a permanent emergent marsh 50–100 m from the breeding pond. At the Dempsey Creek site, *R. pretiosa* apparently undergoes seasonal movements between permanent summer habitat and ephemeral breeding habitat.

We thank Neal Wilkins and Port Blakely Tree Farm for allowing access and for other assistance in conducting field studies on *R. pretiosa* at the Dempsey Creek site.

TESTUDINES

CHELYDRA SERPENTINA (Common Snapping Turtle). **REPRODUCTION**. Twinning is rarely reported in egg-laying reptiles (Aguilar and Casas-Andreu 1991. Herpetol. Rev. 22:98; Petch 1990. Herptile 15:13–16; Castano-Mora 1985. Lozania 52:1–5). Morever, eggs containing twin yolks or developing embryos rarely produce viable hatchlings. There are at least two exceptions (Petch 1990, *op cit.*; Kinkaid 1996. Herpetol. Rev. 27:26), both involving snakes. Twinning has been reported once in turtles (Castano-Mora 1995, *op cit.*) but has never been reported in the common snapping turtle.

As part of an experiment concerning temperature-dependent sex determination, I collected six clutches of snapping turtle eggs from Carrol and Whiteside Counties, Illinois, USA during June 1994. One egg contained two living embryos. This egg, at 10.54 g, was within the mass range of the other eggs in that clutch (8.97–12.4 g). This egg was laid on 5 June 1994 and incubated at ca. 26°C. Living twins hatched on 12 August 1994. The larger hatchling measured 29.1 mm carapace length (CL), 19.8 mm plastron length (PL), and weighed 8.0 g; the smaller measured 16.4 mm CL, 10.5 mm PL, and weighed 1.29 g (clutch mean: 31.6 mm CL, 20.7 mm PL, 9.65 g). The smaller turtle died within a few days of hatching, but the larger is still alive at almost two years post-hatching. This is the first known case of live twins being hatched from one egg in any species of turtle. Both turtles will be deposited in the University of Texas at Arlington Collection of Vertebrates.

Submitted by **DANIEL J. O'CONNELL**, Department of Biology, Box 19498, The University of Texas at Arlington, Arlington Texas 76019, USA; e-mail: oconnell@albert.uta.edu.

CHELYDRA SERPENTINA (Snapping Turtle). **REPRODUCTION.** The maximum reported clutch sizes from snapping turtles in Florida (USA) are only 20 and 21 eggs, both from the peninsular Florida subspecies, *C. s. osceola* (Iverson 1977. Herpetologica 33:205–212; Punzo 1975. J. Herpetol. 9:207–210). Here, we report several larger clutches from northwestern Florida (*C. s. serpentina*) as well as additional ones from *C. s. osceola*. A large female *C. s. serpentina* was observed laying 54 eggs (excavated for counting) in early May 1995 adjacent to a natural wetland in Tallahassee, Leon County (Bob Walker, pers. comm.). The ten largest clutches that we have recorded from *C. s. serpentina* during our ongoing studies of chelydrid nesting ecology along the lower Apalachicola River, Franklin County (Ewert and Jackson 1994. Florida Game and Fresh Water Fish Comm. Nongame Wildl. Prog. Final Rept. NG89-020), were 52, 51 (female maximum carapace length [CL] 320 mm), 46, 44(2), 43, 42(3), and 41.

The maximum known clutch size of *C. s. osceola* remains well below 50 eggs. From Dixie County in northern Florida we dissected 31 eggs (32 corpora lutea) from a female (278 mm CL) collected on 2 March 1979, and 30 eggs from a second female collected on 13 March 1988. Farther south, a female (274 mm CL) collected on 16 March 1988, just south of Lake Jessup in Seminole County, yielded 23 eggs. Another clutch of at least 23 eggs (UF 1090) was collected in 1930 in Alachua County. However, female *C. s. osceola* can grow considerably larger than indicated above; a series of large specimens collected in 1928–1929 from Lake Apopka (Orange County) includes three females (UF 53706, 65675, 53705) measuring 368, 352, and 348 mm CL. Given that female body size and clutch size in snapping turtles are correlated (Iverson et al. 1996. Herpetologica, *in press*; Yntema 1970. Am. Midl. Nat. 84:68–76), this suggests the potential for much larger clutches in *C. s. osceola* than are reported here.

Part of our research was supported by Nongame Wildlife Grant NG89-020, Florida Game and Fresh Water Fish Commission. We thank Woody Miley and Lee Edmiston of the Apalachicola National Estuarine Research Reserve and Isbon Teuton of the Florida Park Service for special help, Bob Walker for sharing his observations, and David Auth for providing data from Florida Museum of Natural History (UF) specimens. MAE also thanks Cory R. Etchberger for field assistance.

Submitted by **DALE R. JACKSON**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA, and **MICHAEL A. EWERT**, Department of Biology, University of Indiana, Bloomington, Indiana 47405-6801, USA.

GOPHERUS AGASSIZII (Desert Tortoise). **DIET.** On 2 August 1996 (0815 h) I observed an adult male *Gopherus agassizii* foraging on an isolated desert hill in Pinal County, Arizona, USA. Closer inspection of the food item revealed it to be a raptor pellet lying in the middle of a disarticulated turkey vulture (*Cathartes aura*) carcass. Verification that the actual food item was the vulture pellet was given by the presence of clumps of hair on the tortoise's beak and nose. The pellet was deposited in the University of Arizona herpetological collection (UAZ 50336).

Extensive literature exists on the diet of *G. agassizii*, which consists primarily of native and exotic grasses, forbs, flowers, and fruits (Grover and DeFalco 1995. Gen. Tech. Rep. INT-GTR316, Ogden, Utah: U.S. Dept. Agriculture, Intermountain Research Station. 134 pp.). Esque (1994. M.S. Thesis, Colorado State Univ., Fort Collins, USA. 243 pp.) and Hansen et al. (1976. Herpetologica 32:247–251) reported mammalian feces, hair, and bones; bird feathers; rocks and soil; reptile scales; and arthropods as small components of *G. agassizii* diets. This is the first reported observation of *G. agassizii* foraging on a raptor pellet. Ingestion of bones in the pellet may have provided supplemental minerals to the tortoise (Esque and Peters 1994. *In* Bury and Germano (eds.), Biology of North American Tortoises, pp. 105–111. Natl. Biol. Surv., Fish Wildl. Res. 13, Washington, D.C.).

I thank Jeffrey M. Howland for his comments on the manuscript.

Submitted by **ROY C. MURRAY**, Nongame Branch, Arizona Game and Fish Department, 2221 West Greenway Road, Phoenix, Arizona 85023, USA.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **NESTING.** On 30 May 1996 at 1145 h, we observed an adult female gopher tortoise (straight line carapace length 293 mm, mass 4.3 kg) atop a recently disturbed pocket gopher (*Geomys pinetis*) mound (circumference 2.5 m) at Naval Air Station Cecil Field in western Duval County, Florida, USA. We probed the mound with the wire shaft of a survey flag and located five eggs approximately 16 cm from the top of the mound, laid in two layers with three eggs on the bottom. We recovered the eggs with soil and released the tortoise on the mound. After approximately five minutes, the tortoise left the mound and walked to a burrow 25.8 m east of the nest site. To the best of our knowledge, this is the first documented use of a *Geomys pinetis* mound as a nest site by *G. polyphemus*.

The burrow was located in disturbed sandhill habitat replanted with longleaf pine (*Pinus palustris*) in 1988 with an estimated canopy cover of 7%. The pocket gopher mound was located in an area of slash pine (*Pinus elliottii*) planted in 1954 with an estimated canopy cover of 38%.

Gopherus polyphemus prefers sandy unshaded areas as nesting sites (Hallinan 1923. Copeia 1923:11–20; Landers et al. 1980. Herpetologica 36:353–361) and in north Florida may nest primarily in or near burrow aprons (Diemer and Moore 1994. *In* Bury and Germano (eds.), Biology of North American Tortoises, pp. 129-137, U.S. Fish and Wildl. Serv., Fish and Wildl. Res. Rep. 13). Conversely, Smith (1995, Bull. Florida Mus. Nat. Hist. 37 Pt. 1(4):97-126) found few nests in or near burrow aprons in north Florida. Data presented here indicate *G. pinetis* mounds may provide alternative nesting sites when available. Researchers conducting surveys for *G. polyphemus* nests should include *G. pinetis* mounds in their sampling.

MALACLEMYS TERRAPIN TERRAPIN (Northern Diamondback Terrapin). **PREDATION.** On 2 May 1996 an adult male *Malaclemys terrapin terrapin* was found near Milford Point in Milford, Connecticut, USA. This turtle was being attacked by at least two unidentified gulls (*Larus* sp.). A local resident interrupted this predation event and immediately brought the turtle to the Connecticut Audubon Coastal Center for potential rehabilitation. All four legs had been severed—the forelimbs at carpal level and the hind limbs slightly proximal to the tarsi, so that tibia and fibula were protruding. The tail had a slight laceration. Head, neck, and shell lacked any obvious injuries. The animal died 28 August 1996 after refusing food. The skeleton currently is retained by the Center for use in education programs. Klemens (1993. Amphibians

and Reptiles of Connecticut and Adjacent Regions. State Geol. Nat. Hist. Surv. Connecticut Bull. 112:1–318) reported that immature terrapins are eaten by a variety of vertebrate and invertebrate predators, but human activities are the prime cause of adult mortality. This may be the first documented case of bird predation on an adult *M. t. terrapin*.

Submitted by **GREGORY J. WATKINS-COLWELL** (e-mail: GJWC@aol.com) and **MATT BLACK** (e-mail: Milfordpt@aol.com), Connecticut Audubon Coastal Center, 1 Milford Point Road, Milford, Connecticut 06460, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). **MORTALITY.** The most common macrobiological source of mortality for turtles is predation by various large vertebrates (Ernst et al. 1993. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C., 578 pp.). Mortality caused by invertebrates is rare but is known to occur in hatchling and juvenile turtles as a result of predation by decapod crustaceans and hemipteran insects (e.g., Stancyk 1982. *In* Bjorndal (ed.), Biology and Conservation of Sea Turtles, pp. 139–152. Smithsonian Inst. Press, Washington, D.C.; Gotte 1992. Herpetol. Rev. 23:80). Here we describe an apparent accidental case of adult mortality caused by a bivalve mollusk.

On 18 June 1996, a dead female *Sternotherus odoratus* (Kinosternidae; carapace length 62.4 mm) was found by M. Henderson in Salado Creek at Camp Tahkodah near Floral, Independence County, Arkansas, USA. The turtle's head was inside the closed shell of a living, gravid female *Ligumia subrostrata* (Unionidae; maximum shell length 73.2 mm; Fig. 1), apparently trapped at the point where the mussel's siphon emerges. We opened the mussel and found the turtle to be unmarked other than the neck being laterally compressed to a width of 2.4 mm by the margin of the mussel's shell. There was no mussel tissue in the turtle's mouth and no obvious damage to the soft tissues of the mussel. The apparent scenario is that the turtle was attracted to the siphon or other soft tissue and put its head (width = 14.3 mm) inside the open mussel, which then closed, resulting in the turtle either drowning or suffocating.

We thank H. Riley and B. Fouts for bringing the specimens to our attention, and J. Harris for identifying the mussel and for discussions on mussel biology.

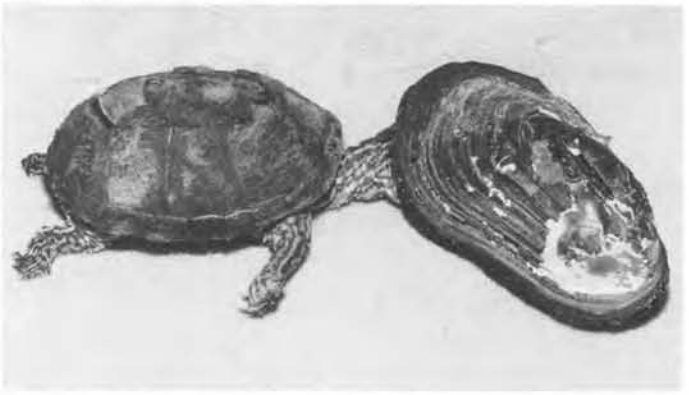

FIG. 1. A common musk turtle, *Sternotherus odoratus*, with its head trapped inside a pondmussel, *Ligumia subrostrata*.

SAURIA

CNEMIDOPHORUS LEMNISCATUS (NCN). **HERBIVORY.** On 16 April 1996 at 1130 h near Las Bocainas, on the road to Adícora, on the eastern coast of the Paraguaná Peninsula, Falcón, Venezuela, one of us (BC) observed two young *Cnemidophorus lemniscatus* eating petals of the flowers of the cactus *Opuntia wentiana*. The flowers were located at ground level; the lizard did not climb the cacti. Paulissen and Walker reported herbivory in *C. arubensis* from Aruba Island, *C. murinus* from Curacao Island, (both Netherlands Antilles) and *C. nigricolor* from Isla La Blanquilla, Venezuela (1994. J. Herpetol. 28:524–526). This is the first report of herbivory in a non-insular species of *Cnemidophorus*.

Submitted by **ABRAHAM MIJARES-URRUTIA**, Centro de Investigaciones en Ecología y Zonas Aridas (CIEZA), Universidad Francisco de Miranda, Apartado 7056, Coro 4101-A, Venezuela, **BORO COLVÉE**, Departamento de Ciencias Ambientales, Universidad Simón Bolívar, Sartenejas, Caracas, Venezuela, and **ALEXIS ARENDS R.**, Centro de Investigaciones en Ecología y Zonas Aridas (CIEZA), Universidad Francisco de Miranda, Apartado 7056, Coro 4101-A, Venezuela.

SCELOPORUS BICANTHALIS (Transvolcanic Bunchgrass Lizard). **PATTERNLESSNESS.** Usually all members of the *Sceloporus scalaris* and *S. aeneus* complexes (of the *S. scalaris* group) of México are marked with two paravertebral series of 6–9 more or less U-shaped dark spots between two distinct dorsolateral light lines 7–8 scale rows apart, and similar but smaller markings in a row between the dorsolateral and lateral light lines. The distinctness of the pattern varies from dull (especially in the *aeneus* complex) to bright (especially in the *scalaris* complex). However, some individuals of some of the included taxa are unicolor above and on sides, or with only faint evidence of the dorsolateral light lines. Unicolor individuals have long been known in populations of *S. s. scalaris* westward from the longitude of Guanajuato (Thomas and Dixon 1976. Southwest. Nat. 20:531) and Zacatecas (HMS, pers. obs.), as well as in *S. s. slevini* (Anderson 1972. J. Herpetol. 6:80), *S. s. unicanthalis* (HMS, pers. obs.), *S. a. aeneus* (Guillette and Smith 1985. Bull. Maryland Herp. Soc. 21:4) and *S. a. subniger* (Smith and Brandon 1971. J. Herpetol. 5:60). They are thought not to occur in *S. bicanthalis* (Guillette and Smith, op. cit.), *S. chaneyi* (Liner and Dixon 1992. Texas J. Sci. 44:426), *S. goldmani* (Smith 1939. Zool. Ser. Field Mus. Nat. Hist. 26:350–353), *S. s. scalaris* east of the longitude of Guanajuato (Thomas and Dixon, loc. cit.) or *S. s. samcolemani* (Liner and Dixon, loc. cit.).

Thus two patternless adult female *Sceloporus* of the *scalaris* group from La Molina, 3 mi E Perote, 8000 ft., Veracruz, are of special interest. They were taken 30 July 1955 along with four juveniles from the same locality, all now under the number UMMZ 112972. All have 2-2 canthals, thus eliminating *S. aeneus* from consideration, but both *S. s. scalaris* and *S. bicanthalis* occur nearby and both possess two canthals although neither is known elsewhere to exhibit patternlessness (except westward from Guanajuato in *S. s. scalaris*). However, that these six represent *S. bicanthalis* is assured by two facts. For one, UMMZ 172753, from nearby at 25 km E Perote on the road to Jalapa, is an adult male with the sharply defined, prominent black gular streaks, sublateral semeions and small size (37 mm SVL) typical of that species (gular streaks less prominent and less well defined, semeions on sides of abdomen, SVL greater at maturation, in *S. scalaris*). Secondly, the larger (48 mm SVL) of the two patternless females contains fully formed

eggs that lack shells, as is consistent with the known viviparity of *S. bicanthalis*. In the oviparous species *S. scalaris*, eggs in a comparable stage of development have a well developed shell, as exemplified by UMMZ 118556, from 2 mi SE Laguna Valderrama, 7800 ft., Zacatecas, 19 June 1957.

On these bases we add *S. bicanthalis* to the list of species of the *scalaris* group of *Sceloporus* in which patternlessness occurs. It remains unknown in the wide-ranging eastern component of *S. s. scalaris*, extending from Tamaulipas to Puebla and westward along the transvolcanic zone to (but not including) Guanajuato.

Submitted by **GREGORY J. WATKINS-COLWELL**, Department of Biology, Sacred Heart University, Fairfield, Connecticut 06432-1000, USA; and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA.

SCINCELLA LATERALIS (Ground Skink). **PREDATION.** Although birds are often acknowledged as feeding on lizards (Pearson 1917. Birds of America, Doubleday & Co., New York), direct observations of predation are relatively rare under natural conditions. On 22 June 1996, we witnessed a barred owl (*Strix varia*) attack an adult ground skink as the lizard crawled through mixed leaf litter composed of deciduous hardwood leaves and pine needles. The weather was cloudy and the air was warm (27°C) and humid. Prior to attacking the lizard, the owl had perched on a narrow white ash (*Fraxinus americana*) limb 3.5 m above the litter surface for about 15 min. During this time, it alternately scanned the forest understory and ground surface, presumably searching for prey. At 1635 h, it cocked its head toward the ground and flew silently to the litter surface where it captured the ground skink in its talons. After eating the lizard on the ground, the owl flew to a nearby perch and resumed scanning the forest understory.

Barred owls have been reported to prey upon a variety of small herpetofauna (Ross 1989. Amphibians and Reptiles in the Diets of North American Raptors. Wisconsin Endangered Species Report 59), however lizards were not included among the prey listed. To our knowledge, the only previous record of avian predation on ground skinks was by Beane and Trail (1991. Herpetol. Rev. 22:99) who reported a pair of nesting bluebirds (*Sialia sialis*) feeding ground skinks to their young. Based on qualitative observations, ground skinks are extremely abundant in the leaf litter of the mixed mesophytic forest where the observations took place (a residential forested area west of the Devil's Millhopper State Geological Site, Gainesville, Alachua County, Florida, USA; Brooks 1967. Ecol. Monog. 37:71–87 for estimates of abundance in similar habitat). As such, it is possible that small lizards could form an important component in the diet of these non-passerine avian predators.

Submitted by **C. KENNETH DODD, JR.**, Biological Resources Division, U.S. Geological Survey, 7920 N.W. 71st Street, Gainesville, Florida 32653, USA, and **MARIAN L. GRIFFEY,** 5222 N.W. 56th Court, Gainesville, Florida 32653, USA.

XANTUSIA VIGILIS (Desert Night Lizard) and ***SCELOPORUS MAGISTER*** (Desert Spiny Lizard). **PREDATION and DIET.** Here, we report evidence of predation on *Xantusia vigilis* by *Sceloporus magister*. We collected a yearling female *S. magister* (71 mm SVL, mass = 13.6 g) on 24 July 1996, 5 km SE of Llano, Los Angeles County, California, USA (34°29'N, 117°46'W, elevation 1120 m). In the laboratory, on 29 July, the *S. magister* deposited a fecal pellet that contained part of a *Xantusia vigilis* body, including sections of dorsal and ventral integument and both hind limbs. Based on the knee-to-knee length of the prey specimen (14 mm) and a sample of living *X. vigilis* (N = 24) from the same locality, we estimate that the *Xantusia* prey would have measured 42 mm SVL and weighed 1.2 g when alive, and therefore was an adult.

Sceloporus magister and *X. vigilis* are abundant at this site, and commonly inhabit Joshua trees (*Yucca brevifolia*) throughout the western Mojave Desert. However, *S. magister* typically climbs Joshua trees and is a diurnal heliotherm and ambush predator, whereas the reclusive *X. vigilis* inhabits fallen branches and other debris, and is rarely observed in the open. This *S. magister* was perched in a Joshua tree when first observed. *Sceloporus magister* sometimes take shelter beneath fallen Joshua tree branches. Despite their common name, night lizards are apparently sometimes active during the day, beneath debris (Stebbins 1954, Amphibians and Reptiles of Western North America. McGraw-Hill, New York. 536 pp.). A daytime encounter beneath fallen Joshua tree branches seems to be the most likely explanation for this instance of predation.

Zweifel and Lowe (1966. Am. Mus. Novit. 2247:1–57) do not mention *S. magister* as a potential predator of *X. vigilis* at their study site, which was within 4 km of our collection site. Likewise, Parker and Pianka (1973. Herpetologica 29:143–152) do not mention *Xantusia* in their analysis of the diet of *S. magister* from the Mojave Desert.

SERPENTES

CROTALUS CERASTES CERASTES (Mojave Desert Sidewinder). **LONGEVITY**. *Crotalus cerastes cerastes* is known to live in captivity up to 11.7 years (Snider and Bowler 1992. Longevity of Reptiles and Amphibians in North American Collections. Herpetol. Circ. No. 21. Society for the Study of Amphibians and Reptiles. 40 pp.). Here we report on a captive *C. c. cerastes* that is presently 28 years old.

In June 1968 Thomas Moisi collected a gravid *C. c. cerastes* from just east of Whitewater Canyon, Riverside County, California, USA. In September 1968 this snake gave birth to five offspring. Today, one of the offspring is still alive in the collection at California State Polytechnic University. This female *C. c. cerastes* is presently 629 mm SVL, 53 mm tail length, and 378 g. It has several tumors, but feeds regularly and apparently is still reproductive, producing unfertilized eggs in 1994 and 1995.

Submitted by **ROBERT H. GOODMAN, JR., GLENN R. STEWART**, and **THOMAS J. MOISI**, Department of Biological Sciences, California State Polytechnic University, Pomona, 3801 West Temple Avenue, Pomona, California 91768, USA.

DENDRELAPHIS CALLIGASTRA (Northern Tree Snake). **DIET**. As is the case for the majority of Australia's snakes, the diet of *Dendrelaphis calligastra* is known only from dissection of a relatively small number of museum specimens (Shine 1991. Copeia 1991:120–131). These dissections revealed that the species preys on frogs (families Hylidae and Myobatrachidae) and lizards (families Scincidae and Gekkonidae).

While conducting fieldwork in rainforest near Paluma in northern Queensland, I caught an actively foraging *D. calligastra* (SVL

= 83 cm, tail length = 35 cm) at ca. 1200 h on a sunny day (25 September 1995). Examination of the snake revealed a prominent bulge, and palpation led to the snake regurgitating two microhylid frogs (*Sphenophryne robusta*). Both were almost completely intact, suggesting that they had been ingested recently, possibly on that day. This is the first record of *D. calligastra* preying on frogs of the family Microhylidae.

Submitted by **GEORDIE A. TORR**, Department of Zoology, James Cook University, Townsville, 4811, Australia.

DIADOPHIS PUNCTATUS VANDENBURGHI (Monterey Ringneck Snake). **DIET**. Ringneck snakes are known to prey on salamanders, small frogs, lizards, small snakes, slugs, and earthworms (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.). On 14 July 1996 (1921 h) we collected a male *Diadophis punctatus vandenburghi* (343 mm SVL, 9.5 g) on the Indian Creek trail in the Los Padres National Forest, Santa Barbara County, California, USA. During the 1.5 h hike back to our vehicles, the snake regurgitated a neonate two-striped garter snake (*Thamnophis hammondii*, 188 mm SVL, 5.0 g). To our knowledge this is the first report of a *D. p. vandenburghi* preying upon *T. hammondii*.

The *T. hammondii* was deposited in the Department of Biological Sciences collection at California State Polytechnic University, Pomona (CSPU Pomona 02245).

Submitted by **ROBERT H. GOODMAN JR.**, Department of Biological Sciences, California State Polytechnic University, Pomona, 3801 West Temple Avenue, Pomona, California 91768, USA, and **DON TATE**, 527 West Alamar Avenue #50, Santa Barbara, California 93105, USA.

ELAPHE OBSOLETA LINDHEIMERI (Texas Rat Snake). **PREY**. At 2345 h on 29 July 1995 at Houma, Terrebonne Parish, Louisiana, USA, I found an *Elaphe obsoleta lindheimeri* (ca. 46 cm TL) at the top of a brick wall wedged along the mortar connections. The snake's body was bulging from having eaten a number of Mediterranean geckos, *Hemidactylus turcicus turcicus*, one of which was partially engulfed in its mouth. The snake was examined and released. The introduced *Hemidactylus* can usually be found on brick walls at night, and retreat under the molding in the upright mortar connections. Although young *E. obsoleta* are known to eat lizards, I am unaware of any reports of feeding on *H. turcicus*. Further, this note documents nocturnal foraging in an otherwise diurnal snake.

Submitted by **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

LAMPROPELTIS TRIANGULUM CELAENOPS (New Mexico Milk Snake). **MAXIMUM SIZE**. An adult female *Lampropeltis triangulum celaenops* collected in May 1996, 2 mi E of Eunice, Lea Co., New Mexico, USA measured 720 mm SVL and 119 mm tail length. This exceeds the previous record, 641 mm total length (Tennant, A. 1984. The Snakes of Texas. Texas Monthly Press, Austin. 561 p.), by 198 mm. The specimen is deposited in the University of New Mexico Museum of Southwestern Biology, Herpetology Division (MSB 60390). Thanks to Douglas Lynn for providing this specimen.

Submitted by **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico, 87504, USA and **TOBY J. HIBBITTS**, 602 Hilltop Circle, Wylie, Texas 75098, USA.

MASTICOPHIS FLAGELLUM (Coachwhip). **PREY.** Feeding behavior in the genus *Masticophis* has been studied by Cunningham (1959. Herpetologica 15:17–19), Hamilton and Pollack (1956. Ecology 37:519–526), and Jones and Whitford (1989. Southwest. Nat. 34:460–467). *Masticophis flagellum* is known to take a wide variety of prey (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Company, Boston, Massachusetts. 336 pp.; Jones and Whitford, *op. cit.*). Here we report on the active pursuit of the lizard *Dipsosaurus dorsalis* and the finding of *Crotalus viridis* in the gut of *M. flagellum*, two prey not previously reported for this species.

On 7 August 1991 in the western Mojave Desert just north of Barstow (San Bernardino Co., California, USA), we observed a small *Masticophis flagellum piceus* (ca. 100 cm total length) moving slowly upslope while flicking its tongue many times within a few seconds. After the snake progressed forward several cm, it would raise its head 6–8 cm and rapidly and repeatedly strike (4–5 strikes observed seven times) its rostrum into the substrate. After each bout of striking, the snake would raise its head ca. 10–12 cm above the ground and observe the area it had struck. We observed this behavior for 11 min. After the seventh striking episode, the snake, while observing the substrate from the raised position, suddenly lunged forward, narrowly missing a desert iguana (*Dipsosaurus dorsalis*) that flushed from the area of the final striking episode. The lizard ran off with the snake in pursuit. After pursuing the lizard for ca. 5 m, the snake aborted the chase and returned to its previous foraging pattern. These observations occurred at about 1000 h and the air temperature was 40.5°C. The snake was engaged in active pursuit of a lizard at relatively high temperatures, in contrast to the change to sit-and-wait tactics at high temperatures noted by Jones and Whitford (*op. cit.*) in the Chihuahuan Desert.

On 25 April 1996 we found a small (ca. 45 cm TL) decomposing western rattlesnake (*Crotalus viridis oreganus*) in the esophagus of a road-killed adult (140 cm TL) male *Masticophis flagellum ruddocki*, on Mocal Road, 0.2 miles southeast of the junction with Crocker Springs Road, Kern Co., California. We do not know if the rattlesnake was taken alive or eaten as carrion (Cowles 1946. Herpetologica 3:121-122; Small et al. 1994. Herpetol. Rev. 25:28).

Submitted by **STEPHEN P. TABOR**, BioEnvironmental Associates, 4209 Landatos Ave, Bakersfield, California 93307, USA, and **DAVID J. GERMANO**, Department of Biology, California State University, Bakersfield, California 93311, USA.

REGINA ALLENI (Striped Crayfish Snake). **SIZE**. The record total body length for *Regina alleni* is 65.4 cm (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). On 1 July 1996, I caught a female *R. alleni* with a total body length of 70.5 cm (SVL = 53.7 cm). She weighed 141.0 g, was not gravid, and no prey items were evident from palping. The snake was captured in a minnow trap, which is part of a standard array of 20 traps. The array is located at Happy Creek Swale (Brevard County, Florida, USA) and is used as part of a long-term monitoring program for amphibians and reptiles of the Kennedy Space Center. Because

the animal is part of an ongoing study, it was given a cohort mark, photographed, and released at the point of capture. Photographs remain in possession of the author. Measurements were verified in the lab by Rebecca B. Smith

Submitted by **JEFFERY P. DEMUTH**, Department of Biological Sciences, Southeastern Louisiana University, Box 814, Hammond, Louisiana 70402, USA.

SONORA SEMIANNULATA (Ground Snake). **ANTIPREDATION.** A *Sonora semiannulata* 30 cm in total length, taken near Mesa, Arizona, USA, was introduced into a terrarium containing a *Micruroides euryxanthus* (Sonoran coral snake), 36 cm in total length, taken in Pinal Co., Arizona. The *Sonora* immediately began to explore the cage. Upon contacting the coral snake, the *Sonora* flung itself wildly as far as possible from the other snake. After a few moments the *Sonora* continued exploring the cage. Three times, as the coral snake detected the rear part of the *Sonora*'s body, it bit that part, but each time the *Sonora* freed itself by a quick jerk. The *Micruroides* eventually secured a firm bite on the *Sonora* about four cm posterior to its head. The *Sonora* thrashed about vigorously, but the coral snake entwined their bodies until they were in a tight ball. Other than a few muscle spasms on the part of both animals, no further movements occurred for several min. Then again the *Sonora* began to struggle violently, untangling itself and resorting to rapid twisting on its own axis. The coral snake nevertheless retained its hold, allowing itself to be dragged around, but was not, however, completely passive during this phase, gradually working its jaws toward the head of its prey by quick, jerky release of its grip and instant purchase of a new grip a short distance in advance. It thus worked its way to a point about 1.3 cm from the prey's head.

Now the *Sonora* executed a remarkable maneuver by gripping itself with its jaws about five cm back of its head, forming a complete loop. The *Micruroides* continued its grip-release-grip advancement over the head of the *Sonora* and around the loop onto its body, whereupon the *Sonora* released its grip upon itself and renewed its struggle to escape. The *Micruroides* continued undeterred its advancement toward the *Sonora*'s head, which again bit itself as before when the coral snake reached its neck. The predator was again "derailed" by the maneuver, and continued on to a third enactment of the scenario, briefly losing its grip before doing so. Upon the fourth enactment, the coral snake chewed violently on the prey's head as it reached that point, whereupon the *Sonora* released its grip upon itself. Instantly its entire head was engulfed by the coral snake, although the *Sonora* continued to writhe vigorously for several min. Only after ingestion of most of its body did the *Sonora* seem to weaken.

The looping behavior of the *Sonora* may be a widespread antiophiophagous resort not only in that genus but also in others that serve as prey for coral snakes and other ophiophages. Behavior similar to this has been observed (pers. obs.) in lizards preyed upon by snakes. Confined to cages, prey are unable to escape, but under natural conditions looping might sometimes be effective in disorienting predators so that prey can take advantage of being released or of having directed the predator to the prey's tail.

SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309,USA.

TANTILLA HOBARTSMITHI (Southwestern Black-headed Snake) and ***TANTILLA NIGRICEPS*** (Plains Black-headed Snake). **COLORATION.** Reports of albinism in snakes are common in the herpetological literature. Hensley (1959. Michigan St. Univ. Biol. Ser. 1:135–159) reported albinism in 16 species, Dyrkacz (1981. Recent instances of albinism in North American amphibians and reptiles. SSAR Herp. Circ. 11:1–31) reported on 28 species, and Bechtel (1995. Reptile and Amphibian Variants Colors, Patterns, and Scales. Krieger Publ. Co., Malabar, Florida. xvii + 206 pp.) illustrated 27 species.

On 5 July 1996 we (BRT, JHG) collected an adult *Tantilla hobartsmithi* (SVL 154 mm, tail 57 rnm, 1.7 g), a partial albino with erythrophores (Dyrkacz, *op. cit.*). This snake was collected from a 18.9 L pitfall trap placed along a road in Guadalupe Canyon, ca. 1.1 rd km E the New Mexico/Arizona state line, Hidalgo Co., New Mexico, USA. In life the eyes and tongue were bright pink. The dorsal coloration was cinnamon (Color 39) and the ventral color was peach red (Color 94) (Srnithe 1975. The Naturalist's Color Guide. Am. Mus. Nat. Hist., New York). The specimen was deposited into the Division of Herpetology, Museum of Southwestern Biology, University of New Mexico (MSB 60389).

A search of the MSB collection yielded two additional partial albino *Tantilla*. MSB 26019 is an adult male *T. nigriceps* (SVL 177 mm, tail 52 mm). This specimen was collected on 11 May 1973 by S. Ivey, ca. 1 air mi N New Mexico Hwy 44 bridge over the Rio Grande, Sandoval Co., New Mexico. The specimen is completely pink in preservative with no differentiation of color on the dorsal or ventral surfaces. The eyes and tongue are pink. MSB 38536 is a juvenile (sex undetermined) *T. hobartsmithi* (SVL 87 mm, tail 26 mm) collected on 20 April 1980 by B. Pietruszka from 27 km N and 1.6 km E of Whites City (T22S R25E SW1/4 SS1/4 Sec 1), Eddy Co., New Mexico. The specimen is a pale straw-color in preservative. There is a small, faded, light-brown spot that covers the posterior edge of the parietals, and no differentiation of color on the dorsal or ventral surfaces is evident. It is likely that both preserved specimens have faded somewhat in preservative. This is the first report of albinism in the genus *Tantilla* (Dyrkacz, *op. cit.*).

We thank William G. Degenhardt and Toby J. Hibbitts for calling the MSB specimens to our attention.

TECHNIQUES

Use of Silt Fencing and Funnel Traps for Drift Fences

KEVIN M. ENGE
Florida Game and Fresh Water Fish Commission
Route 7, Box 3055, Quincy, Florida 32351, USA
e-mail: enge@freenet.fsu.edu

Drift fencing, commonly used to inventory herpetofaunal communities, typically biases against catching large snakes, turtles, and species with arboreal, fossorial, or sedentary habits (Campbell and Christman 1982; Dodd 1991; Gibbons and Semlitsch 1982). Whereas a variety of drift-fencing materials have been employed, most researchers use aluminum or galvanized valley (i.e., flashing) because it is readily available, relatively easy to install, self-standing, and durable. Proper installation of metal valley requires digging a trench, however, a difficult task in wetlands with unconsolidated substrates or standing water.

The Florida Game and Fresh Water Fish Commission (FGFWFC) has begun using a new drift-fencing material, silt fencing, to survey herpetofaunal communities in both hydric and terrestrial habitats. Silt fencing, a woven polypropylene material used to control sediment runoff at construction sites, is available from several suppliers in various widths and lengths with variable spacing for attached stakes. A 30.5 m long roll of silt fencing from a Tallahassee, Florida, supplier cost $27.50, 1/3 the cost of an equal length of 50.8 cm wide galvanized or aluminum valley. We used silt fencing of 91.4 cm width that came attached by heavy staples to 122 cm long wooden stakes placed at ca. 2.5 m intervals.

The woven material of silt fencing is permeable to water, which decreases pressure on the fence and minimizes trap displacement by flowing water deflected along the fence. Silt fencing can be installed in situations with flowing water, if the velocity and volume of the water is not too great. If installed across small streams, silt fences should be placed to allow some water to flow underneath the fence. If the flowing water carries a high sediment load, sediment accumulation along the upstream side of the fence may eventually render the fence ineffective.

Silt fences can be installed quickly in wetlands with soft substrates lacking large roots (e.g., muck) by sequentially pounding the stakes into the ground. The bottom edge of the silt fence should be held taut during installation; after installation, any sagging material along the top edge can be tightened by stapling it to an adjacent stake. Stakes should be sunk deep enough so that ca. 15 cm of the lower skirting of the silt-fencing material can be pushed below the surface of the substrate with a garden spade. Tamping along the fence with one's feet after the fence is installed seals up the trench.

In terrestrial habitats, or hydric situations with large roots or extensive root mats, silt fencing can be installed by the usual technique of digging a trench (see Corn 1994). Because silt fencing is much more flexible than valley, the depth and overall symmetry of the trench are not as critical as when installing valley. Subsurface roots or rocks also can be left intact with silt fencing without sacrificing the integrity of the fence. A guide rope to dig along helps while installing drift fences in standing water or in dense ground cover.

Typically, silt fences are not reused, especially if plant roots have grown through the buried portion of fencing. Silt fences used to sample wetland habitats for five months were removed and reused the following year before being discarded, however. No noticeable deterioration of silt fences occurred in studies lasting one year or more, but broken stakes had to be replaced occasionally.

The FGFWFC has used single 15 m long drift fences to sample hydric habitats and a three-fence array design, modified from Jones (1986) by the addition of single- and double-opening funnel traps, to sample both hydric and terrestrial habitats. Pitfall traps (e.g., 19-liter buckets) could be used along silt fences, although the flexible material of silt fencing would make proper placement of pitfall traps more difficult than along metal valley. Properly constructed and placed funnel traps will capture the same species, except for large turtles, as pitfall traps and are better than pitfall traps at capturing certain anurans and large snakes (pers. observ.). Funnel traps can function during high water levels, unlike pitfall traps.

Funnel traps are fashioned from 91.4 cm wide aluminum window screen fastened together with ordinary office staples, forming finished traps ca. 86 cm long. I typically use double-opening funnel traps 20 cm in diameter with funnel openings 5 cm in diameter and single-opening funnel traps 25 cm in diameter with a funnel opening 6 cm in diameter. Funnel traps are shaped into semicircles, so the flat side can fit tightly to the substrate. All traps are provided with sponges to help prevent desiccation of trapped animals.

Funnel traps typically are held in place along the fence by leaning shade covers over them. Shade covers consist of 41 x 41 cm squares of 6 mm thick masonite. Traps may be staked in place or even attached to the material of the fence to prevent displacement by flowing water or animals. In aquatic situations, I opt to keep traps tight to the substrate instead of suspending them along the water surface.

Drift-fencing studies using silt fencing and valley in comparable habitats produced similar trapping success, although arboreal lizards may have been less susceptible to trapping along silt fences because the woven material was climbed more readily. *Anolis carolinensis* commonly were observed climbing silt fences and hiding under shade covers, but they were not captured in proportion to their observed abundance.

Screen funnel traps along silt fences in Florida captured 21 frog, 18 salamander, one crocodilian, twelve turtle, ten lizard, and 32 snake species. Traps captured many aquatic species, including two species each of *Siren, Pseudobranchus*, and *Amphiuma*; three species of *Regina*; four species of *Nerodia*; *Farancia abacura*; and *Alligator mississippiensis* < 1 m long. If traps were placed tight to the fence and substrate, they efficiently sampled small animals, such as amphibian larvae and metamorphs, reptile neonates, *Acris* spp., *Gastrophryne carolinensis, Pseudacris ocularis, Eurycea quadridigitata, Scincella lateralis, Storeria occipitomaculata*, and *Tantilla relicta*. Immature individuals of large turtle species (i.e., *Apalone ferox, Chelydra serpentina, Deirochelys reticularia, Gopherus polyphemus, Pseudemys floridana, P. nelsoni*) and large snakes (e.g., *Agkistrodon piscivorus, Crotalus adamanteus, Drymarchon corais, Masticophis flagellum, Pituophis melanoleucus*) were captured occasionally. Species with arboreal (e.g., five *Hyla* spp., *Anolis carolinensis, Eumeces laticeps, Elaphe obsoleta, Opheodrys aestivus*) and fossorial tendencies (e.g., *Ambystoma talpoideum, A. tigrinum, Rana capito, Eumeces egregius*) also were captured, although some of the species, particularly hylids, were under-sampled. I was successful in trapping species infrequently seen in Florida, including *Hemidactylium scutatum, Pseudotriton montanus*, and *Agkistrodon contortrix*.

Silt fencing is more cost-efficient than valley for short-term studies because it is less expensive and requires less installation time.

Silt fencing may be more effective than valley during high water periods because of its greater height. Silt fencing also may prove more of an obstacle to large snakes or climbing animals than valley because of its greater height, although the woven material and presence of stakes on one side of the fence may make silt fencing easier to climb.

Acknowledgments.—I thank Kenneth Benfield, David Crowe, James Godwin, and Dirk Stevenson, who helped install drift fences and collect data, and the other FGFWFC biologists involved in implementing and administering drift-fencing surveys: Nancy Douglass, Douglas Runde, Stephen Stiegler, and Kristin Wood. The FGFWFC's Bureau of Nongame Wildlife and Bureau of Wildlife Management supported and funded this research, and various FGFWFC personnel reviewed earlier drafts of this manuscript. I thank Stephen Busack for editorial suggestions.

A Bone Biopsy Technique for Determining Age and Growth in Sea Turtles

RUTHELLEN C. KLINGER
Virginia Institute of Marine Science, College of William and Mary, Gloucester Point, Virginia 23062, USA
Present address: Department of Fisheries and Aquatic Sciences University of Florida, 7922 NW 71st Street, Gainesville, Florida 32653, USA

Knowledge of the age of animals studied in the wild is necessary for accurate growth and life history studies. Techniques for determining age typically involve marking the animal with an internal chemical dye, external tattoo, tag, or by notching a body part; recaptures of marked animals allow researchers to document growth over a known time period.

Oxytetracycline, when injected into muscle tissue, will deposit in all calcified structures and fluoresce under ultraviolet light (Frost et al. 1961; Harris 1960). For age validation in fish, researchers have used cross sections of oxytetracycline-labeled otoliths (Beamish and Chilton 1982), dorsal spines and fin rays (Beamish and McFarlane 1983; Cass and Beamish 1983; Meunier and Pascal 1981), and vertebrae (Gruber and Stout 1983; Holden and Vince 1973; Smith 1984). Phalanges (Castanet 1985; Smirina 1972), flat bones (Castanet and Naulleau 1985) and femurs (Roberts et al. 1988) have been used in amphibians and reptiles. With the exception of studies using marked phalanges and fin rays, methods for age and growth determination require that the animal be sacrificed; this poses a problem in studies of endangered species. To address this limitation, we developed a non-lethal bone biopsy technique that removes a section of tetracycline-labeled humerus showing the fluorescent band and all growth layers (Klinger and Musick 1992).

From 1985 to 1990 fourteen *Caretta caretta* (59.1–96.2 cm straight-line carapace length) and two *Lepidochelys kempi* (55.0 and 68.2 cm SCL) were biopsied. The turtles were anesthetized with a combined solution of 10 ml Ketamine HCl (100 mg/cc) and 1 ml Acepromazine (10 mg/cc) [Fort Dodge Laboratories, Fort Dodge, Iowa, USA] by direct administration (at a rate of 20–30 mg/kg body weight) into the dorsal cervical sinus. Turtles became torpid within five to ten minutes and showed no evidence of discomfort or distress. The mid-ventral surface of either foreflipper was incised distal to the scapulo-humeral joint, and the triceps brachii and internal brachial muscles were separated to expose the humerus. Involuntary muscle contractions noted at initial incision ceased at the point of deep muscle separation. A Michelle Trephine bone corer (Miltex, Lake Success, New York, USA) was used to excise a 3 mm (for *L. kempi*) or 6 mm plug (for *Caretta*) from the flat ventral surface of the humerus just distal to the deltopectoral crest (see Zug et al. 1986). The incision was closed with non-absorbable nylon suture material and biopsied turtles were radiographed post-surgery.

Turtles were kept dry for 24 h (eyes moistened every hour) and then placed in shallow pools. Typically, sutures were removed after two weeks and the turtles were released into the wild after a one month recovery period. All but one loggerhead survived the operation and recovery period. One loggerhead that we biopsied survived the recovery period but was found dead on a North Carolina beach one month after its release. The exact cause of death for each of these turtles is unknown. Both *L. kempi* survived the biopsy procedure and were released.

Long term effects of the 1985 biopsy procedure are suggested by the condition of a single loggerhead recaptured in 1987 and 1988. Radiographs taken of the site of biopsy showed partial filling of the bone structure. When recaptured again in 1988, apparently healthy, radiographs showed the 1985 biopsy site to be completely filled in.

Bone biopsy is a useful tool for acquiring age and growth records of vertebrates without the undesirable consequences of lethal sampling. Although a licensed veterinarian is required to conduct the procedure, it is relatively simple and logistically feasible for most turtle monitoring programs. While sample size is limited, available recaptures of biopsied turtles suggest that this technique does not compromise the swimming behavior of these migratory animals.

Acknowledgments.—Sarah Bellmund, Richard Byles, John Keineth, and Deborah Barnard assisted us in sea turtle sampling and data collection. Patricia Dolan aided us with veterinary procedures. This project was funded by the Virginia Department of Game and Inland Fisheries, Non-Game Species Fund.

Cloacal thermistor or thermocouple probes and temperature-sensitive implanted or ingested radiotransmitters have been used successfully to measure internal body temperatures of reptiles under field and captive situations (Avery 1982; Kenward 1987). Both methods are invasive and require capture and handling of animals. A new method that utilizes a non-contact temperature reader equipped with a laser-sighting device is gaining popularity, particularly within the zoo community (R. Hudson and J. Wines, pers. comm.). With this type of device, skin surface temperature can be read accurately from a distance of several meters (depending upon animal size) with little or no disturbance to daily activity patterns. While the non-contact temperature reader permits accurate measurement of skin surface temperature, it does not provide direct information about internal body temperature. We used a non-contact temperature reader in captive juvenile Cuban rock iguanas, *Cyclura nubila*, to develop a method for experimentally deriving the relationship between skin surface temperature and internal body temperature.

Mid-dorsal skin surface temperatures of 41 juvenile iguanas (mass range 120–850 g) were measured from a distance of 1 meter over 30 days during March and April, 1995. We used a Raytek Raynger™ PM non-contact thermometer equipped with an FDA class IIIa laser sighting device (accuracy rated to $\pm$ 1°C; Raytek, Inc., Santa Cruz, California, USA) to measure temperatures between 1200 and 1300 h each day. All individuals had been fed and allowed to bask for at least 30 minutes. Mean ambient temperature within the enclosure was 28.5 $\pm$ 0.2°C and five ceramic infrared heating elements distributed throughout the enclosure provided localized basking areas with temperatures up to 45°C. Mean skin surface temperature for the 41 juveniles was 35.2 $\pm$ 0.2°C.

In order to derive a formula for estimating internal body temperature, we characterized the relationship between body mass, skin surface temperature, and internal body temperature between October, 1995, and January, 1996, in 9 of the original group of 41 juveniles (mass range 210–1450 g). Each iguana was placed in a restraint directly under a ceramic heating element that had been allowed to cool to an ambient temperature of 27°C. After the heating element was again turned on, internal body temperature was monitored once per minute for the next 35 minutes by a thermistor probe inserted into the cloaca; mid-dorsal skin surface temperature was measured using the non-contact thermometer at the same time. The relationship between skin surface temperature (T_S) and internal body temperature (T_b) was determined by regression for each of the 9 juveniles over the period of linear temperature increase. A second regression equation describing how the slope of this relationship changed with each individual's body mass was then derived:

$$\text{Slope of } (T_S, T_b) \text{ relationship} = -0.0003(\text{mass}) + 0.926 \quad (1)$$

As expected, the slope of the (T_s,T_b) relationship (range 0.457–1.143) was shallower for animals with larger body mass due to their slower rate of heating compared to smaller animals.

Using equation (1), the slope of the (T_s,T_b) relationship can be determined for any juvenile *Cyclura nubila*, provided its mass is known. At any ambient temperature (T_a), the animal's estimated internal body temperature can be predicted from its skin surface temperature using the following equation:

$$\text{Estimated } T_b = (\text{slope of } [T_s,T_b] \text{ relationship})(T_s - T_a) + T_a \quad (2)$$

To examine the predictive accuracy of this method, we again took mid-day skin surface temperatures on 8 of the original group of 41 juveniles using the non-contact thermometer in January, 1996. At testing, the ambient temperature was 26.1°C. Immediately following measurement of skin surface temperature, each iguana was captured and its internal body temperature taken with a cloacal thermistor probe; predicted internal body temperatures differed from measured internal body temperatures by 1.7 ± 0.3°C (Table 1). Overestimates were slightly more common than underestimates (5 of 8 cases), but the magnitude of error was similar in both directions. These results suggest a fairly high degree of predictive ability for this technique, particularly given the limits of the non-contact temperature reader. Having validated this method, we predicted mean internal body temperature for the original 41 juveniles to be 33.8 ± 0.1°C.

TABLE 1. A comparison between measured and predicted internal body temperatures in 8 juvenile *Cyclura nubila*.

Mass (g)	T_s °C	(T_s,T_b)	Predicted T_b °C	Measured T_b °C	Predicted minus actual
115	27.8	0.891	27.6	25.0	2.6
500	36.1	0.776	33.9	32.3	1.6
750	33.4	0.701	31.2	30.0	1.2
1050	33.4	0.611	30.6	31.1	-0.5
1200	27.2	0.566	26.8	24.5	2.3
1450	30.0	0.491	28.0	26.1	1.9
1650	32.8	0.431	29.0	29.5	-0.5
1800	31.7	0.386	28.3	31.1	-2.8

This method of temperature estimation probably will work well for any juvenile *Cyclura* within our tested range of body masses and may be useful for approximating internal body temperatures for other iguanid lizards possessing similar surface area-to-volume ratios. When applied to a 6.65 kg adult, however, this method underestimated internal body temperature by 5.2°C. While it is possible empirically to generate an equation for how the slope describing the relationship between skin surface temperature and internal body temperature varies with body mass for lizards of any size, equation (1) is best applied only to iguanids with body masses of 1800 g or less.

Acknowledgments.—We gratefully acknowledge the help of John Phillips in deriving the equations, and thank Jeff Lemm, Juniper Ross, and Trent Pearson for assistance in data collection. This work was supported by National Science Foundation Conservation and Restoration Biology Grant DEB-9424471.

An Inexpensive Method for Creating Spaghetti Tags for Marking Trionychid Turtles

MICHAEL J. DRESLIK
Zoology Department, Eastern Illinois University
Charleston, Illinois 61920, USA
e-mail: cumjd1@uxa.ecn.bgu.edu

Marking techniques for turtles range from shell notching to tagging (Ferner 1979). Notching can cause infection and tags may be lost. Spaghetti tags—long, numbered strands of hollow pliable plastic inserted into an incision made in the turtle's carapace, and knotted at both ends to prevent loss—have been used successfully for marking trionychids. The main drawback in spaghetti tag use is the expense.

During the course of my study at Round Pond, Gallatin County, Illinois, USA, I devised an inexpensive method for making spaghetti tags. I purchased a three meter section of Romex wire containing eight differently colored wires within an outer sheath. After first stripping the outer sheath, I cut each of the eight wires into 10 cm lengths and removed the copper core, leaving only the colored plastic sheath. This produced 240 inexpensive tags and, by using one to four tags per turtle, a total of 4680 unique combinations can be produced. To insert the tags on the soft-shell turtles (primarily *Apalone spinifera*), I made a small incision in the perimeter of the carapace and threaded the unknotted end of the tag through. Next I square-knotted the portion fed through the incision, leaving about 1.5 cm between knots to allow for unrestricted growth. Finally, I removed the excess plastic sheath beyond the last knot.

Acknowledgments.—Funding for this project was provided by the Illinois Endangered Species Protection Board, Eastern Illinois Council on Faculty Research, Eastern Illinois Honor Program Undergraduate Research Award, the Chelonian Research Foundation, and the E.I.U. Graduate Summer Research Assistantship Award. I thank E. O. Moll for his insightful review of this manuscript, S. D. Busack for his thorough review, and J. R. Dreslik for aid in making tags.

A Non-Invasive Method for Sustained Elevation of Steroid Hormone Levels in Reptiles

ROSEMARY KNAPP

and

MICHAEL C. MOORE
Department of Zoology, Arizona State University
Tempe, Arizona 85287-1501, USA
e-mail (MCM): michael.moore@asu.edu

Manipulating circulating levels of hormones is integral to many studies of behavioral endocrinology. Steroid hormone supplementation generally is achieved through single or repeated injections of the hormone when examining acute effects (Mason and Adkins 1976), or through chronic implants of crystalline hormone encased in Silastic® tubing (DeNardo and Sinervo 1994; Hews et al. 1994) or introduced in pellet form (Tokarz 1987) to determine longer-term effects. Injection utility is limited by a relatively short dura-

tion of hormone elevation, and implant utility is limited by stress effects of the surgery required to insert the implant. Our studies on the role of corticosterone in mediating agonistic behavior in male tree lizards (*Urosaurus ornatus*; Knapp and Moore 1995) required a method that would elevate plasma corticosterone levels for at least 24 h, but did not require surgery. We did not want the control animals to experience surgery-associated increases in corticosterone levels. Because reptilian skin and many of its secretions contain lipids (Mason 1992), we explored the feasibility of delivering corticosterone, a lipophilic molecule, transdermally. We report here an inexpensive, non-invasive and simple method of delivering exogenous corticosterone over a period of at least 24 h.

Our method involves the use of a dermal patch securely fastened to the skin of the animal. These dermal patches may also prove useful to investigators wishing to non-invasively elevate levels of a variety of compounds. In our laboratory, the patches have been used to elevate testosterone, progesterone (D. K. Hews, unpubl.), and estradiol (E. L. Lacy, unpubl.) levels in tree lizards. This method holds promise for elevating levels, in a non-invasive manner, of any lipophilic molecule that can cross the skin.

Dermal Patch Construction and Application.—The dermal patch is a piece of adhesive bandage secured to the back of the animal by means of a transparent dressing. Steroid dissolved in sesame oil is placed on the adhesive bandage, with a piece of vinyl electrical tape used to prevent leakage of the oil onto the dressing (Fig. 1). Sizes of patch components will differ with the size of the reptile; our adult male tree lizards (3–5 g) measured 50–60 mm snout-to-vent. Our dermal patches had three parts: (1) a 4 x 3 mm patch of gauze and backing from a Johnson & Johnson Sheer Band-Aid® (Junior size); (2) a 5 x 10 mm piece of vinyl electrical tape; and, (3) an 8 x 20 mm piece of Johnson & Johnson Bioclusive® transparent dressing (cut while still attached to its paper backing). We used Johnson & Johnson products because they worked; we assume that other comparable products could be used as long as the thickness of the gauze is similar. If using Johnson & Johnson products, use of a "Junior" size adhesive bandage is important, however, as the gauze from larger-sized bandages is too thick to hold its shape when cut into small pieces.

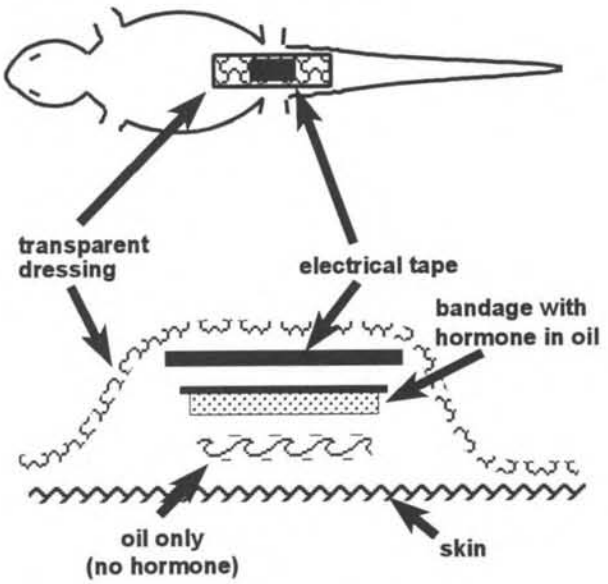

FIG. 1. Schematic drawing of a dermal patch.

Patches are assembled prior to application; to facilitate construction and transport, the adhesive portion of self-stick removable note paper (e.g., Post-It®) is taped, adhesive-side up, to the inside of the bottom of a petri dish dedicated to either hormone or control patches. Assembly has two stages. First, using forceps, a piece of vinyl electrical tape is placed adhesive-side up on the note paper and a piece of bandage (gauze-side up) is then placed on the electrical tape. Second, using the forceps, a piece of transparent dressing is peeled off its paper backing and placed adhesive-side up in a different location on the adhesive note paper. The previously assembled electrical tape-adhesive bandage portion of the patch now is pressed onto the transparent dressing, thereby also pressing the transparent dressing more firmly onto the note paper adhesive. The patch is now "face up" relative to how it will be placed on the animal. A pre-determined amount of sesame oil/hormone mixture is applied to the surface of the bandage, distributing the oil over the surface of the patch. The amount and concentration of the hormone mixture must be determined separately for each species and hormone in test runs to verify that the hormone levels produced in the animal are in the desired range.

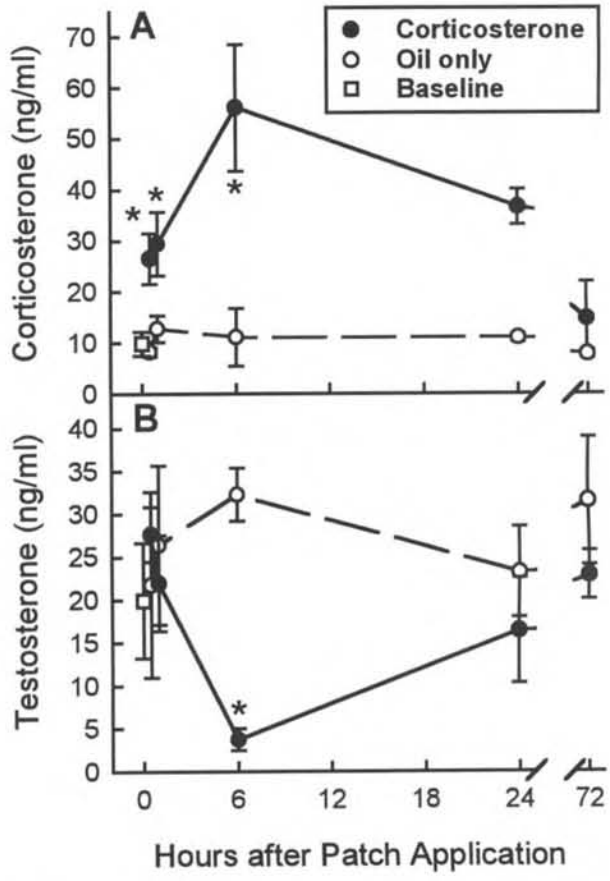

FIG. 2. Mean (± SE) plasma levels of corticosterone (A) and testosterone (B) following application of dermal patches; N = 4–8 for each mean. * = significantly different from oil group (Mann-Whitney U tests: $P < 0.05$).

Prior to placing the patch, we use a microcapillary tube to dab pure sesame oil (no steroid) in the area where the patch will go. This helps ensure contact between patch and skin, and may delay diffusion of steroid into the animal by providing a hormone-free zone across which the hormone must diffuse. We apply the patch along its long axis to the dorsal surface between the hind legs (Fig. 1). In this location the lizard cannot remove the patch, and such placement does not impede the male's social displays. The patch is removed from the petri dish and pressed firmly into place

using forceps. The transparent dressing's holding power comes from its overhang beyond the electrical tape; if necessary, additional pieces of transparent dressing may be used to ensure that the patch is attached securely.

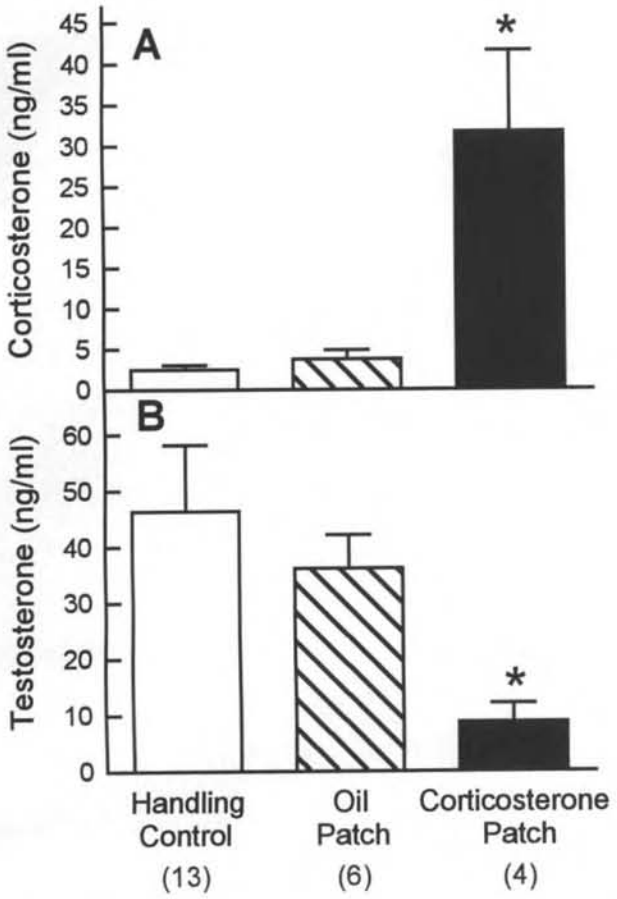

FIG. 3. Mean (± SE) plasma levels of corticosterone (A) and testosterone (B) in free-living male tree lizards 24 h following application of a dermal patch containing 13.5 μg corticosterone in sesame oil (Corticosterone Patch) or containing only oil (Oil Patch). Handling Control males did not receive a patch. Sample sizes are in parentheses below each treatment group; * indicates significantly different when compared with other treatment groups (Newman-Keuls tests: $P < 0.01$).

Time Course of Corticosterone Delivery.—Adult male tree lizards were housed individually in 40-liter glass tanks in the laboratory for 3–6 days to allow corticosterone levels to stabilize after the stress of initial handling (Moore et al. 1991). After the adjustment period, each male was given a dermal patch containing 4.5 μl of either corticosterone in sesame oil (10 μg corticosterone/μl oil; total = 45 μg), or sesame oil only. Blood samples were collected (orbital sinus) from five different subgroups of males 0.5, 1, 6, 24, and 72 h following application of the dermal patch, and from an additional subgroup of males that did not receive patches (to determine baseline hormone levels). Each male was bled only once. Plasma levels of corticosterone and testosterone were determined by radioimmunoassay following ether extraction and Celite chromatography according to methods in standard use in our laboratory (see Knapp and Moore 1995). We measured testosterone levels because glucocorticoids are known to suppress androgen levels (Tokarz 1987).

The dermal patches successfully delivered steroid over 24 h. Forty-nine of 51 patches remained attached for 24 h; six of 12 patches still were attached after 72 h. Males wearing dermal patches containing corticosterone had elevated plasma corticosterone levels when compared to control males at all time points between 0.5 and 24 h (Fig. 2A), but testosterone levels were significantly lower only at 6 h in males wearing patches containing corticosterone when compared to control males (Fig. 2B). At all times except 0.5 h, mean testosterone levels were lower in males wearing corticosterone patches than in males wearing patches containing only oil, although not significantly so.

Use of Dermal Patches in Free-Living Lizards.—An exploratory study demonstrated that these patches may be used for at least 24 h on free-living lizards. Dermal patches prepared the night before were applied to lizards captured by noosing and marked with a unique combination of paint marks. We used a lower concentration of corticosterone (3 μg corticosterone/μl oil) in this trial to obtain elevated circulating levels of plasma corticosterone more within physiological levels. Males received a patch containing 4.5 μl of either corticosterone in sesame oil (total = 13.5 μg corticosterone) or pure sesame oil and then were released after a total handling time of less than 10 minutes.

The following day we returned to the site to recapture marked males and collect blood samples as described above. Blood was also collected from additional males captured on the same days that blood samples were collected from males receiving patches. These additional males served as controls for handling involved with application of dermal patches and thus provided baseline hormone levels.

Dermal patches were successful on free-living animals; of 23 males receiving patches, we were able to resight 15 the following day (7 of 12 experimental and 8 of 11 control). All males resighted had the dermal patch still attached, but in four cases the patch appeared looser than when first applied. For those males from which we were able to collect sufficient blood samples, males wearing patches containing corticosterone had significantly higher plasma corticosterone and significantly lower testosterone levels than males wearing control patches or than those serving as handling controls (Fig. 3A and 3B, respectively, analyses of variance: both $P < 0.01$).

The dermal patches described here successfully elevated plasma corticosterone levels in laboratory-held and free-living lizards for at least 24 h. Manipulating the amount of corticosterone applied to the patch allows some control over the magnitude of the effect on plasma corticosterone levels. In each situation, animals receiving patches containing corticosterone exhibited significantly lower plasma testosterone levels than those males receiving patches containing only oil. However, the time at which testosterone levels were suppressed differed between laboratory-housed and free-living lizards (6 h and 24 h, respectively). This difference may reflect the fact that circulating levels of testosterone in laboratory-housed male tree lizards are usually lower than those of free-living males, even when corticosterone levels are not artificially manipulated (see Moore et al. 1991).

Acknowledgments.—We thank Larry Nienaber for his suggestions and for his care of lizards in the laboratory. We also thank Ilana Quain for field assistance. An Inexpensive Chamber for Collecting the Excretory Products of Tadpoles

DAN COGĂLNICEANU

Bucharest University, Faculty of Biology, Department of Ecology
Splaiul Independentei 91-95, 76201 Bucharest, Romania
e-mail: danco@bio.bio.unibuc.ro

Many studies have considered the importance of anuran larvae in aquatic ecosystems (e.g., Leibold and Wilbur 1992; Seale et al. 1975) but their role remains insufficiently understood. While feeding preferences and growth rates have been documented (Duellman and Trueb 1986), virtually nothing is known about the rate of excretion. Through non-selective grazing and filtering (Sekar 1992; Viertel 1990), tadpoles significantly alter the structure of phytoplankton and periphyton and, consequently, the structure of the entire food-web. Portions of their fecal pellets reach the sediments, but some of their excretory products are dissolved or suspended in the water column. A chamber initially designed for use in the study of assimilation and excretion rates in mussels (Stanczykowska et al. 1975) was adapted for the study of the rate of excretion in tadpoles. This chamber allows determination of the amount of fecal material that eventually reaches the sediments.

The chamber can be constructed easily from a clean, empty plastic bottle (a) and a test tube (b) (Fig. 1). A hole is drilled in the cap of the bottle to fit the test tube firmly while not allowing water leakage. Access by the tadpole to the collection tube is restricted by a net (c) fixed on a plastic tube formed in a circle of appropriate size. Choice of the mesh size for the net depends on the size of the tadpoles used in the experiment; a 1–2 liter plastic bottle is well-suited for tadpoles of 2–3 cm in length. A similar device for smaller tadpoles can be assembled from a glass funnel fused to a test tube with silicone.

I have used up to 12 chambers at one time. Caps with fitted test tubes, and plastic rings with nets attached, are fitted to the chambers and aged tap water is added. Tadpoles used in the experiments should be housed individually and fed (*ad libitum*) daily, but not during the experiment. All experiments involve one weighed and/or measured tadpole per device and last from 6–24 h at the desired temperature. Time can be partitioned into 2–3 shorter periods to determine dynamics of the rate of excretion (e.g., three periods of 8 h/chamber instead of one 24-h period). Feces are collected in a previously weighed test tube and dried at 60°C for 72 h. Excess water can be removed easily before drying after the test tubes are centrifuged. At the end of the experiment, tadpoles are weighed and dried under the same conditions. Portions of the food used to feed the tadpoles can be dried also; these dried samples can be used for chemical analyses to estimate nutrient balance. A small plastic or metal device with pre-weighed food bound in agar (Taylor et al. 1995) can be added to the chamber. The rate of excretion thus can be estimated according to the feeding rate. Tadpoles near metamorphosis (Gosner [1960] stages 40–46) should not be used, since they have a low rate of excretion that eventually stops completely during the final stages of metamorphosis (Dauça and Hourdry 1983).

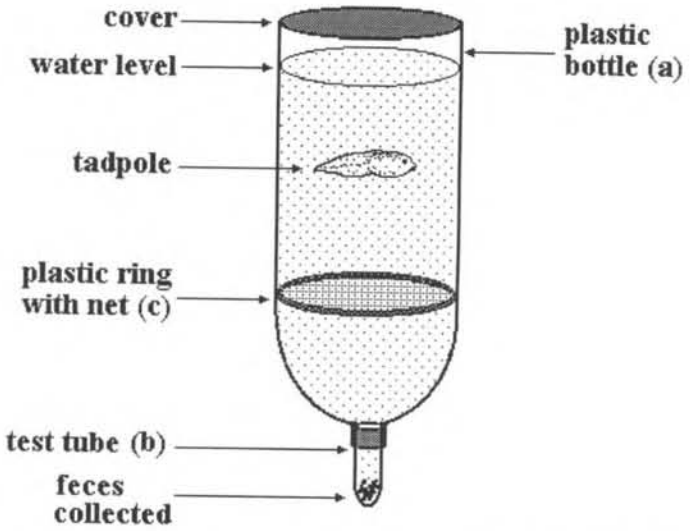

FIG. 1. The chamber used for studying the rate of excretion in tadpoles.

A preliminary study of excretion rates in *Pelobates fuscus* showed that the dry weight of the feces represented 19.7 ± 2.4% (range = 8–50%) of the dry weight of the tadpole. If loss of weight due to respiration is ignored, the dry weight of the feces represents almost one sixth of the initial dry weight of the tadpole. Tadpoles may accumulate sand in their guts; to avoid confounding the data, tadpoles should be kept in aquaria without any solid substrate several days prior to experimentation. The study of the rate of excretion in different species fed a variety of diets may contribute to a more complete understanding of the importance of tadpoles in aquatic communities.

CHELONIAN RESEARCH MONOGRAPHS, NUMBER 1

Now Available

Chelonian Research Foundation is pleased to announce the publication of the first volume of *Chelonian Research Monographs*, published July 1996:

The Galápagos Tortoises:
Nomenclatural and Survival Status
by
PETER C.H. PRITCHARD

This important scientific contribution presents an overview, critique, and updating of the nomenclature of Galápagos tortoises, along with a comprehensive historical review of the survival status and population trends of all the known populations. The volume is available in hard or soft cover and consists of 85 pages of text profusely and richly illustrated in color with 65 plates and photographs (12 in black and white and 53 in full color) ilustrating all described and recognized taxa, including extinct forms, and 11 maps showing geographical distributions of all populations.

Both hard and soft cover editions are available for immediate delivery.

HERPETOLOGICAL HUSBANDRY

A Safe Procedure for Mite Eradication

RICHARD R. MONTANUCCI
Department of Biological Sciences
Clemson University, Clemson, South Carolina 29634-1903, USA

Mites present serious health problems for captive squamate reptiles. The snake mite, *Ophionyssus* sp., for example, has been implicated as a vector for various disease organisms (Caimin 1948; Frye 1981; Marcus 1983). Mites can also consume significant quantities of blood from the host, leading to potentially life-threatening anemia (Mader 1989). Once established in a reptile cage, these ectoparasites can increase rapidly and spread to other cages (Mader, *op. cit.*).

The common chuckwalla, *Sauromalus obesus*, is a natural host for two species of mites: *Hirstiella pyriformis* and *H. trombidiiformis* (Mader et al. 1986; Werman 1980). Although high density mite infestations are likely to develop in captivity, free-living chuckwallas have been found occasionally with heavy mite loads (Hunter 1966; Werman, *op. cit.*).

Mahaney (1995) described a simple method of mite control in which masking tape was placed around the inside perimeter of cages housing San Esteban chuckwallas, *Sauromalus varius*. With only the center of the tape attached to the cage walls, the edges were free to trap mites to the adhesive.

A different, safe procedure is discussed here that involves substantial reduction of the mite population, followed by interception of gravid females and, thus, interruption of the life cycle at oviposition. This procedure was developed after several unsuccessful attempts (use of No-pest strips; washing lizards and cages) were made to control the lizard mite, *Hirstiella pyriformis*, in a group of common chuckwallas.

Seven chuckwallas were housed in three cages (154 x 69.5 x 56.5 cm). Cages 1 and 3 housed a pair of adult chuckwallas, while cage 2 contained a pair and a juvenile female. Mite infestations in cages 1 and 2 were judged to be moderate. At this infestation level, mites were visible on the lizards and several mites could be observed crawling on the cage walls and glass front at any time. Cage 3 had a heavy infestation where dozens of mites were observed on the chuckwallas, cage walls and glass at any time. Additionally, the lizards exhibited rubbing and scratching behavior (pruritus).

The eradication procedure was initiated on 20 April. The lizards were removed from the cages. The sand substrate was discarded, while the rocks used for shelters and basking sites were washed thoroughly with hot water and dishwashing detergent. Cage walls and glass were sponge-washed with warm water and detergent. After the entire cage was air-dried and visually determined to be free of mites, the cage walls were examined for small crevices which may become oviposition sites for mites. These were sealed with silicon sealant. The cage interior was simplified to a single shelter, a basking site comprised of several rocks, and newspaper substrate replaced the sand.

All seven chuckwallas then were washed with Rep-Rinse (Cal-Tex Naturals, Austin, Texas, USA), a non-toxic formulation containing purified water, docusate sodium, proprietary compound, and hendecenoic acid. A second washing was performed after four days. For thorough washing, a child's soft-bristled toothbrush was used to remove mites from between scales and a cotton Q-tip was used to swab the periorbital areas, tympanic recesses, involutions around the vent, and skin folds of the oral commissure. The chuckwallas were examined visually three days after the second washing and a few mites (larvae and deutonymphs) were observed on each. The assumption was made that the mites could not be removed totally from the chuckwallas, an assumption based on previous experiences that washing the lizards failed to remove all the mites. Additional washings could lead to undue stress (manifested by the lizards going off feed), and other potential problems developing later, such as skin fungus or necrotic dermatitis.

The mites depend on the chuckwalla for nutrition, but utilize its rocky retreats for protection of eggs, quiescent stages, and adults (Werman 1980). It was hypothesized that the mite population could be completely eradicated if gravid females and egg cases (ca. 2 mm oblong and tapered, whitish structures), could be found and destroyed. The next step in the procedure, therefore, was to intercept females as they matured and left the host to lay eggs. Cage inspections began one week after the lizards had received the second washing. With the simplified cage, egg cases were only found on the undersides of rocks at interfaces with other rocks or the floor. To destroy the female mites and their egg cases, the rocks were washed and the newspaper flooring was replaced on a twice-weekly schedule. All rock surfaces were sprayed thoroughly with a strong jet of cold water from a garden hose. The rocks were then sun-dried. Visual inspection confirmed efficacy in removing mites and egg cases from the rocks. The use of detergent at this point was deemed unnecessary. Any mites observed on the glass, cage walls or floor were removed with a paper towel dampened slightly with Windex® glass cleaner (S.C. Johnson & Son, Inc., Racine, Wisconsin, USA). This cleaner, because it is toxic, was used cautiously around the lizards.

The effects of this procedure became quickly obvious. Four to eight mites with egg cases were discovered in each cage during the first or second inspections. However, by 20 May, none was found in cages 1 and 3, while only three gravid mites were found in cage 2. On 31 May, no mites were found in cage 2, and thereafter, inspections were continued weekly until 28 June. At that time, it was judged that total eradication had been accomplished. This was confirmed by visual inspections of the cages on 10 August.

Using this procedure, it is possible to eliminate a serious mite infestation in about one month. Although follow up inspections continued over four weeks, it might be prudent to continue inspections for at least six weeks after apparent elimination of the mites. Two aspects of this procedure are of paramount importance. First, simplification of the cage environment reduces the number of potential ovipositional sites, greatly facilitating the discovery of mature female mites and egg cases. Second, the twice-weekly environmental cleaning schedule is imperative to intercept gravid mites, or at least to destroy eggs before hatching. Mites are capable of rapid reproduction; for example, the common snake mite, *Ophionyssus natricis*, lays up to 90 eggs at a time, and the interval between oviposition and hatching is about 30 hours (Mader 1989). Rep-Rinse was selected simply because it is a non-toxic formulation, but theoretically any other safe and recommended product could be used to achieve the initial reduction in number of mites on the host. The "masking tape method" described by Mahaney (1995) could probably not control mites since ovipositional sites remained in the lizards' environment. Mahaney's method is perhaps better regarded as one of containment that could be an important adjunct to this procedure by preventing gravid mites from dispersing and ovipositing on the exterior cage surfaces, and eventually reaching other cages.

Acknowledgments.—I thank Jay Chance, Jimmy McGuire, Tony Mills, Lester Milroy III, and Jeff Wines for providing lizards and/or field assistance. Steve Bennett, Orange County Vector Control District, California, kindly identified the mites and provided useful information. Two anonymous reviewers and the section editor provided helpful comments on a previous draft of the manuscript. Chuckwallas were collected under California Department of Fish and Game permit nos. 0301 and 9044, and an Arizona non-resident hunting license.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send three copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover): R. Kathryn Vaughan (lizards, amphisbaenians, crocodilians, Sphenodontia); Charles W. Painter (amphibians); or Paul A. Stone (snakes, turtles). Authors are encouraged to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a text-only version of the file.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1–41; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

RHYACOTRITON KEZERI (Columbia Torrent Salamander). **BEHAVIOR**. Courtship has not been reported in any species of *Rhyacotriton* (Leonard et al. 1993. Amphibians of Oregon and Washington. Seattle Audubon Society. viii + 168 pp.). On 18 March 1995, two male *R. kezeri* were observed in apparent combat, likely related to the courtship of a partially concealed female ca. 25 cm from the site. The smaller of the two males grasped the tail of the other with its mouth and maintained this hold for well over a minute. During that time the two twisted and rolled a distance of 10–15 cm. The salamanders then became aware of the observer's presence and immediately separated and retreated into the forest litter.

This observation was made on a small flat area above a sword fern ca. 10 m up from the bottom of a small, steep-sided, rocky ravine ca. 150 m from the Columbia River in T9N, R7W, sec. 12, Willamette Meridian, Washington, USA. Rain had fallen for the previous 12 h. Water was flowing at the bottom of the ravine. The air temperature was ca. 7°C. The site is in a dense mixed forest of alder, hemlock, spruce, Douglas fir, cedar, and big leaf maple.

ANURA

BUFO HOUSTONENSIS (Houston Toad). **BEHAVIOR**. Juvenile *Bufo houstonensis* were studied at Bastrop State Park, Bastrop Co., Texas, USA from 7 June–15 July 1993. Observations were made during the morning (ca. 0900–1200 h), afternoon (ca. 1330–1530 h), and early evenings until dusk (ca. 1700–1930 h). Searches also were made at night (ca. 2100–2300 h). Climatic conditions included daily rain during the first two weeks and hot, humid weather the remaining four weeks.

Site 1 was a large (ca. 7.6 m wide at top), partly sunny ravine contiguous with a man-made, 4-ha lake located at the northeast end of the park. The soil at the bottom of the ravine was loose and sandy, with scattered debris that the toads used for cover. Metamorphosing toads emerged from a shallow extension of the lake continuous with the ravine. This area of the lake contained the largest concentration of juvenile toads within the study area (> 25 individuals observed at one time). The introduced fire ant (*Solenopsis invicta*), a known predator of juvenile *B. houstonensis* (Freed and Neitman 1988. Texas J. Sci. 4: 454–456), appeared to be absent from Site 1.

During the day, most juveniles at Site 1 were scattered throughout the bottom of the ravine, with a few found in drier sites at the top of the ravine, which was ca. 8–13 m from the lake shore. At dusk, a few individuals hopped down the side of the ravine toward the bottom. During the first two weeks, the toads were dispersed more widely throughout Site 1. Once the rains ceased, the toads became concentrated within the ravine closer to the lake. Toads were not found at the top of the ravine during the dry period.

At dusk, the young toads in the ravine either moved under cover objects or made small depressions in the sand. The toads formed depressions by moving their hindlimbs side to side, thrusting them out at a 45° angle from the body, and bringing them back to the normal position. This was repeated several times. Once settled, some toads did not move for periods of up to 25 minutes, then they moved 5–70 cm to a new site, and repeated the same movements. They would then remain immobile until dark. Other toads made only one depression and stayed in it until evening. The depressions made during the day were used for feeding, while the depressions made just before dusk were used for cover. We could not locate young toads at this site after dark indicating they may have burrowed into the loose soil.

Site 2 was an old dump area (ca. 0.1 ha) with five small, temporary rain-filled pools (ca. 15 cm deep) scattered throughout the area. The edges of the pools were covered primarily with pine needles, leaves, and grasses. Most of the site was flat with little vegetation or shade and dry, compact soil. This soil type appeared inconsistent with known habitat because *B. houstonensis* has difficulty burrowing into the densely packed soil (Bragg 1960. Southwest. Nat. 5:106). The pools at Site 2 dried up at the beginning of July.

The 15 juvenile *B. houstonensis* observed at Site 2 were dispersed more than those at Site 1. There were no concentrations of toads near pool edges as at Site I, although a few individuals were found around the edge of the site after the third week. During the rainy period, the toads were found throughout the site. However, when rains stopped and the surface soil dried, they disappeared from the area. Five toads were found in a ravine ca. 40 m southwest of Site 2. These toads may have originated from Site 2 because other temporary pools were not found nearby. Toads were not found at night at either site. The young toads at Site 2 may use the sandy soil available within the ravine for burrowing. Fire ant mounds were found at this site.

The absence of *S. invicta* within the ravines may play an important part in the survival of the young toads. If this is the case, toads metamorphosing within ravine areas have a better chance of survival than toads emerging from drier, upland areas. More research is needed to indicate whether ravines within *B. houstonensis* habitats are indeed critical to their survival.

Two types of feeding behavior were observed in *B. houstonensis* juveniles: sit-and-wait and active search. Sit-and-wait behavior involved digging into the sand as described above and waiting for prey. The toads would lunge out with their hind legs, scoop up the food item with their tongue, and ingest it.

Active search behavior consisted of hopping or crawling within a small area foraging for prey. The ants taken at this site were not *S. invicta*, but a smaller, inoffensive species. When a young toad would spot a moving object such as an ant, it oriented itself to face it, moved toward it, captured it, and ingested it. It then continued to forage for more food. An example of an aborted active search feeding behavior involved one toad that oriented toward a large worm, moved quickly up to it, but turned and hopped away just as quickly. The toad appeared to be attracted to the movement of the worm, but it may have been too big to ingest. The animal then resumed its active search for prey.

Juvenile *B. houstonensis* were found to be entirely diurnal. The toads were active during the morning until early evening, even during the hottest period of the day. The few young toads found at night, although alert, did not exhibit signs of movement or feeding behavior.

We extend our gratitude to Dede Armentrout for her help and support during the project. Thanks go to Gwilym Jones and John E. Cadle for comments and criticisms on the manuscript, and to Van Wallach for his continued support. Special thanks to Rhonda Roland Shearer whose enthusiasm and funding made this project possible.

TESTUDINES

ERETMOCHELYS IMBRICATA (Hawksbill Sea Turtle). **MORPHOLOGY.** We report the capture of 24 *Eretmochelys imbricata* in the Ogasawara (Bonin) Islands, Japan, from 1975 through 1995 (Table 1). Although *Chelonia mydas* (green turtle) rookeries are known from these islands, no nestings of *E. imbricata* have been reported. All 24 *E. imbricata* were caught by hand, hook and line, or spear in the coastal waters. Measurements are: mean standard straight length = 49.5 cm, SD = 14.8, range = 34.2–85.6 cm, N = 23; mean body weight = 20.1 kg, SD = 23.0, range = 3.8–81.0 kg, N = 22. Thirteen of these turtles were released with plastic flipper tags; none has been recaptured. Partially developed coral reefs around the islands provide habitat for this species. Blood samples were collected from the two most recently captured turtles for a DNA stock identification study.

CROCODYLIA

CAIMAN LATIROSTRIS (Broad-snouted Caiman). **NEW POPULATIONS and UNDESCRIBED HABITAT.** In the coastal regions of southeastern Brazil, the presence of *C. latirostris* often is associated with mangroves (IUCN 1982. The IUCN Amphibia - Reptilia Red Data Book. Part 1. IUCN. Gland. Switzerland; Vanzolini 1993. Papéis Avulsos Zool. 38:107–154). Until 1990, at least six isolated populations were known to occur along the coast in the state of São Paulo (Carretero et al. 1996. *In* Mateos and Mañosa (eds.), Memoria de Resultados del Segundo Viaje de Reconocimiento Científico a Regiones poco Conocidas del Parque Estadual Intervales, Estado de São Paulo, Brasil. Universitat Barcelona). In 1991, a population was reported from a flooded depression surrounded by lowland Atlantic rainforest close to the Serra de Paranapiacaba at Funil, Parque Estadual Intervales, 70 km from the Atlantic coast (Guix et al. 1992. Grupo Estud. Ecol. Ser. Doc. 4:38–94). Nevertheless, there are no reports of populations from any mountain zone of the Serra do Mar Chain, an area covered by hillside Atlantic rainforest.

From 1–12 August 1994, the population of *Caiman latirostris* in the Funil area was monitored, and a new population was found in the Alecrim region, also in Parque Estadual Intervales.

The Alecrim region is part of a V-shaped valley located in the southwest part of Parque Estadual Intervales (24°20'S, 48°15'W; 38,356 ha). This is traversed by the Pilões River (also called Rio Formoso by local people), and ranges from 70–1046 m. Vegetation formations include lowland Atlantic rainforest (between 70 and 100/150 m), and hillside Atlantic rainforest (between 100/150 and 1046 m); both mature and secondary forests occur in the area.

At the Alecrim site, adult and juvenile caimans were seen active (water temperatures of 19–28°C) by day and night in a lagoon formed in 1986 by the opening of a forest road which dammed a 1.5 m wide clear-water stream. The lagoon has a surface area of 400 m^2 and is situated at an elevation of 200 m. It is surrounded by old growth secondary Atlantic rainforest on the hillsides and is bordered by dense vegetation composed of *Merostachys* sp., bamboo (Poaceae), shrubs (e.g., *Miconia* sp., *Leandra* sp., Melostomataceae) and trees. The lagoon had no dense aquatic vegetation, but there were many fallen branches and trunks in the water, and the bottom was covered by thick leaf litter.

The maximum number of individuals seen simultaneously in the lagoon was 13, distributed as follows: 4 adults (size range 120–150 cm total length); 2 sub-adults (60–80 cm); and 7 juveniles (30–40 cm). Only juveniles and subadults were seen basking outside the water, on semi-submerged trunks. No individuals were found in the surrounding rivers and streams (total distance sampled: 7 km).

The Funil Region is part of a broad sedimentary valley (Vale do Ribeira) and is close to the hillsides of the Serra de Paranapiacaba, in the southeast part of Intervales. The main river is the Rio Felipe (also called Rio Braço Grande). Elevations range from 40 to 200 m. Vegetation consists of secondary lowland Atlantic and mature hillside Atlantic rainforests.

At the Funil site, juveniles and adults were active by day and night in two small lagoons (about 210 and 400 m^2, respectively; elevation 40 m). The first of these is within the Park and the second one is 17 km ESE from the former. Both were bordered by dense vegetation (e.g., *Chusquea bambusoides* [Poaceae], *Scleria* spp. [Cyperaceae], and small herbaceous plants). Another juvenile caiman was seen in a pool of 140 m^2 sited 24 km ESE from the first one and near a small township. The vegetation surrounding these lagoons was composed of successional shrubland with scattered trees and young secondary lowland Atlantic rainforest. Five individuals were observed at the Funil site, as follows: 2 adults, 2 subadults, and 1 juvenile.

No caimans were seen in the rivers and streams inside and outside the reserve (total distance sampled: 20 km). However, their presence was reported by local people one month before the expedition.

The presence of juveniles implies the presence of breeding adults at both Alecrim and Funil. Nevertheless, the number of adults detected was very low and it is possible that both populations are too small to survive by themselves, in the absence of connections to other nearby populations. The Alecrim and Funil localities are separated by 37 km straightline. The Funil population could be connected with others in the Ribeira Valley region, which is large (ca. 3000 km^2) and contains many rivers and streams suitable for caimans.

Caiman latirostris has long been known to occur in eutrophic lagoons and rivers surrounded by subtropical semi-deciduous forests within the Paraná basin (IUCN, *op. cit.*). However, the Atlantic rainforest of coastal Brazil is evergreen and the mountain streams and rivers are oligotrophic. In Alecrim, no open areas around the lagoon were available.

Finding *C. latirostris* in a small lagoon at 200 m altitude on a hillside covered by Atlantic rain forest is of special interest. First, it opens the possibility that the Serra do Mar coastal chain of mountains of eastern Brazil does not necessarily represent a barrier for the dispersion of this species. Second, the presence of a reproductive population in a new habitat confirms the great capability of this species to colonize both fresh and brackish waters in tropical and subtropical regions along a latitudinal gradient from 5° to 34° S (see also IUCN, *op. cit.*). Third, the conditions at these sites provide an interesting ecological context for analyzing the natural history traits of this species in the region.

Thanks are due to Fundação Florestal for logistic support and to William E. Magnusson (INPA) and Carlos Yamashita (IBAMA) for comments and suggestions in the earlier draft of the manuscript.

Submitted by **JUAN C. GUIX, XAVIER SANTOS, ALBERT MONTORI, GUSTAVO A. LLORENTE,** and **MIGUEL A. CARRETERO**, Departamento Biologia Animal (Vertebrats), Facultat de Biologia, Universitat de Barcelona, Av. Diagonal, 645, E-08028 Barcelona, Spain.

LACERTILIA

COSYMBOTUS CRASPEDOTUS (Frilly Gecko) and ***C. PLATYURUS*** (Flat-tailed Gecko). **GLIDING BEHAVIOR.** Gliding is distinguished from parachuting when the angle of descent is greater than 45° from the vertical (e.g., Norberg 1990. Vertebrate Flight, Springer-Verlag, Berlin; Oliver 1951. Am. Nat. 85:171–176). Using this criterion, the agamid *Draco* is classified as a glider, whereas the gekkonid *Ptychozoon* generally is considered to be a parachuting organism (e.g., Reyner 1981. Symp. Zool. Soc. Lond. 48:137–172; but see Heyer 1970. Herpetologica 26:317–319). Gekkonid lizards of the genus *Cosymbotus* have a lateral membrane from axilla to groin and a fringed tail. These features resemble those of *Ptychozoon* but are less developed. Smith (1935. The Fauna of British India Including Ceylon and Burma, Taylor and Francis, London) stated that the membrane of *Cosymbotus* might not function for parachuting or gliding. Cott (1940. Adaptive Coloration in Animals, Methuen and Co. Ltd., London, 508 pp.) suggested that the lateral membrane and tail fringe act as screens obliterating the shadow of body and tail.

On 25 December 1992, in a dipterocarpaceous forest near a trail in Forest Recreation Park, Penang Island, Malaysia, we found an adult female *C. craspedotus* (58 mm SVL) perching on a tree trunk at a height of about 7 m. We dislodged the gecko from its perch with the pliable tip of a long fishing rod. After parachuting straight down about 2 m, it suddenly stopped falling, and glided about 1.5 m in horizontal distance at about 60° from the vertical. When we tried to catch it in a net, it changed its direction and landed on the branch of another nearby tree at a height of about 4 m. During gliding, its membrane was extended laterally. When we prodded it again, it parachuted 1 m, glided 1 m at 45°, landed on the trunk of another tree at a height of 2 m, and climbed up 2 m. On the third capture attempt, it parachuted 1.5 m, glided 0.5 m at 45°, landed on the trunk of the first tree at a height of 2 m, and climbed up 3 m. After dislodging it again, the *C. craspedotus* parachuted 3 m, glided 3 m at 45°, and landed on the ground. There was no wind.

On 19 December 1995, we found an adult female *C. platyurus* (46 mm SVL) perching on the trunk of a rubber tree at a height of 9 m in a rubber plantation, near the Klong Plu Waterfall, Chang Island, Thailand. After dislodging this gecko, it parachuted straight down 6.5 m, changed its direction, glided 1.5 m horizontally, and landed on the same tree at a height of 1.5 m. The glide angle was almost 60° from the vertical, and its membrane was extended during gliding. There was no wind.

Our observations show these species do have the ability to glide and change direction while falling. All previous observations of *Ptychozoon* estimated glide angles of 45° or less (Russell 1979. Zool. J. Linn. Soc. 65:233–249). Our observations constitute the first confirmed records of gliding among gekkonids in natural habitats.

We thank M. Matsui for providing opportunities to visit southeast Asia and A. Mori for kindly reviewing the manuscript. The research was supported by a Monbusho International Scientific Research Program (Field Research: No. 4041068 and 06041066).

EMOIA IMPAR (Blue-tailed Pacific Copper-striped Skink). **REPRODUCTION.** The Pacific populations of copper-striped skinks, formerly referred to *Emoia cyanura*, recently were split into two species: *E. cyanura* and *E. impar* (Ineich 1987. Bull. Mus. natn. Hist. nat., Paris, 4è sér., section A, n° 2:491–494; Ineich 1987. Ph.D. Thesis, Université des Sciences et Techniques du Languedoc, Montpellier, 515 pp.; Ineich and Zug 1991. Copeia 1991:1132–1136) based on differences in coloration, scalation, and ecology; allozyme and DNA sequencing data (Guillaume et al. 1994. Copeia 1994:1042–1047; Bruna et al. 1995. Copeia 1995:981–983) have confirmed their distinctiveness.

Eggs, commonly laid underground, rarely are found for either species. In French Polynesia, where both species always occur syntopically, there are few field observations on the eggs and deposition sites for either species. A series of eggs and hatchlings (BMNH 1903.10.16.25) in The Natural History Museum are thus of particular value. The series consists of 14 freshly hatched juveniles (four of them melanistic), 136 full eggs, and 294 empty egg shells, all of which were found in an empty coconut shell (BMNH) with one of the three top "eyes" opened, probably by a rat attempting to eat the nut, and collected on 11 April 1903 by J. Nicoll at Tahiti Island, Tautira (Taravao Peninsula). All of the 14 hatchlings are *Emoia impar*. This series of eggs and hatchlings clearly demonstrates communal egg laying for *E. impar*. I suggest that *E. cyanura* and *E. impar* use different reproductive sites. We have always found both species in syntopy at all prospected localities, and their relative abundance varies between 30% to 70% according to elevation of the site. My studies of reproductive periodicity show that both species reproduce year around in French Polynesia, with a peak in reproductive activity from October to March (Ineich 1987, op. cit.).

I thank C. J. McCarthy (BMNH) for permitting examination of the material, and G. Zug and T. Schwaner for their comments on this note.

Submitted by **IVAN INEICH**, Muséum national d'Histoire naturelle, Laboratoire de Zoologie (Reptiles & Amphibiens), 25 rue Cuvier, F-75005 Paris, France, and Centre de l'Environnement, Antenne EPHE, BP 1013 Papetoai, Moorea, French Polynesia.

POLYCHRUS ACUTIROSTRIS (Bicho-preguiça). **REPRODUCTION.** The arboreal polychrotid lizard *Polychrus acutirostris* is distributed throughout tropical open vegetation formations of South America, ranging from the Paraguayan Chaco, through the central Brazilian Cerrado, to the Caatinga in northeastern Brazil (Vanzolini et al. 1980. Répteis das Caatingas. Academia Brasileira de Ciências, Rio de Janeiro. 161 pp.). The reproductive biology of *P. acutirostris* has been studied in the Caatinga (Vitt and Lacher 1981. Herpetologica 37:53–63), but no data are available regarding the time between oviposition and eclosion and the size of hatchlings. Herein we report on the development of a clutch of thirteen eggs laid in the lab on 1 Nov 1995, seven days after a gravid female *P. acutirostris* was collected in Cerrado vegetation surrounding Brasília (15°47'S, 47°55'W). The timing of oviposition agrees with data presented by Vitt and Lachner (*op. cit.*), that eggs are laid during the wet season, which in Brasília extends from October to April. The clutch was kept in a flask containing vermiculite, which covered the eggs and was kept moist. The first egg hatched on 29 Feb 1996, 114 days after oviposition. Four more eggs hatched the next day (01 Mar 1996), followed by seven eggs on 02 Mar 1996, and the last egg hatched on 03 Mar 1996. The timing of hatching agrees with the suggestion made by Vitt and Lachner (*op. cit.*) that eggs of *P. acutirostris* will hatch near the end of the rainy season. Data for 13 hatchlings: mean body mass = 0.9 g (SD = 0.1, range = 0.8–1.1, N = 13); mean SVL = 41 mm (SD = 1.4, range = 38–43); mean tail length = 70 cm (SD = 2.4, range = 65–75).

MEDITERRANEAN REPTILES. PREDATION. We report data on the diet of two sympatric gull species at two Mediterranean sites to assess the effect of their predation on reptiles. The study was carried out from 1993–1995 at the Ebro Delta and the Chafarinas Islands. The Punta de la Banya (NE Spain: 40°37'N, 00°35'E Ebro Delta N.P.) is a flat peninsula of 2500 ha with a mosaic of salt marshes and small dunes dominated by psammophilous vegetation. The reptile community at this site is formed by *Psammodromus algirus* and *Malpolon monspessulanus*. The Chafarinas (Melilla SE Spain: 35°11'N, 3°46'35"E) are three small volcanic islands 4.5 km off the Moroccan Mediterranean coast. The reptilian community here is more speciose than at Punta de la Banya and is formed by *Trogonophis wiegmanni, Hemidactylus turcicus, Saurodactylus mauritanicus, Tarentola mauritanica, Chalcides ocellatus, Chalcides paralellus, Podarcis hispanica* and *Coluber hippocreppis*.

Two sympatric species of gulls breed at both sites: Audouin's gull (*Larus audouinii*) and the yellow-legged gull (*Larus cachinnans*). The diet of these species was studied by collecting the food regurgitated by chicks and adults when they were handled for banding. Observations also were made from a blind at the two sites in order to assess the predation of Audouin's gull on reptiles: 451 and 926 h were spent at the Ebro Delta and the Chafarinas Islands respectively (Audouin's gulls group size: mean ± SD = 41.04 ± 40.50, N [number of censuses] = 1419).

Table 1 shows the number of reptiles found in the regurgitated food samples collected from both species and colonies. Only two regurgitates of the yellow-legged gull in the Chafarinas Islands contained reptilian prey: one (collected on 5 April 1995) had one individual of *Trogonophis wiegmanii* (SVL = 143.6 mm) and the other (collected on 25 April 1995) contained two individuals of *Trogonophis wiegmanii* (SVL = 72.9 and 76.6 mm). Two interactions between gulls and reptiles were observed from the blind: on 24 April 1994 we recorded a capture and ingestion of an individual of *Chalcides ocellatus* by an adult Audouin's gull in the Chafarinas Islands, and on 3 June 1994 an adult Audouin's gull tried to capture an individual *Psammodromus algirus* without success in the Ebro Delta. However, of the 557 regurgitates identified from the blind (with 577 identified prey items) no reptilian prey were delivered during courtship or chick feedings. We collected 419 remains and 1227 pellets in the gull nesting colonies, but only a few reptilian remains were found; all of them were prey of the yellow-legged gull. In the Chafarinas Islands we found the remains of *Bufo mauritanicus* (probably from the nearby Moroccan coast, SVL = 103 mm) and a young *Coluber hippocreppis* (SVL = 633 mm). While in the Ebro Delta we found the remains of a young *Malpolon monspessulanus* (SVL = 530 mm).

Our results suggest that predation of Audouin's and yellow-legged gulls on reptiles was occasional, at least in these study sites.

We are grateful to Miguel Angel Carretero and an anonymous referee for valuable comments on an earlier draft of this paper and to Joan Carles Abella for his help in the field work. Robin Rycroft from SAL improved the English text. Research funds were provided by the Instituto para la Conservación de la Naturaleza ICONA.

TABLE 1. Percentage of occurrence of reptiles found in regurgitated food of Audouin's gull, *Larus audouinii* (= LAAU), and the yellow-legged gull, *Larus cachinnans* (= LACA). The breeding population of Audouin's and yellow-legged gulls are also shown for 1994.

	Ebro Delta		Chafarinas Is.		
	LAAU	LACA	LAAU	LACA	TOTAL
Breeding pairs	10.143	1.653	4.136	1.333	
No. regurgitates	315	186	315	295	1.111
No. of prey items	657	472	607	846	2.582
% occurrence of reptiles	0	0	0	0.23	0.002

AMPHISBAENIA

LEPOSTERNON INFRAORBITALE (Two-headed Snake). **REPRODUCTION.** Information regarding the laying, incubation and hatching of the eggs of amphisbaenians is sparse. This note describes the hatching of a clutch of eggs of *Leposternon infraorbitale* Berthold, 1859. It is probable this is the first observation of the actual hatching of amphisbaenian eggs; details also are given of the site where the eggs were collected.

Goeldi (1897. Zool. Jahrb., Abt. Syst. Geogr. Biol. Thiere, 10(5):640–676) reported a clutch of eggs of *Leposternon microcephalum* found in March near Rio de Janeiro, Brazil. They had been laid in a pile of bricks and tiles which was inhabited by ants of the genus *Camponotus*. However, the author only gave the dimensions of the eggs. Gans (1971. Bull. Am. Mus. Nat. Hist. 144:379–464) examined numbers of eggs in collections, mostly in a poor state of preservation.

On 20 February 1994, six eggs of *Leposternon infraorbitale* were found in the grounds of the Cacao Research Centre (Centro de Pesquisas do Cacau - Comissão Executiva do Plano da Lavoura Cacaueira, CEPEC-CEPLAC) in the town of Ilhéus on the south coast of the state of Bahia, Brazil (14°45'S, 39°13'W). One of the eggs was opened for species identification immediately after collection (Fig. 1). The specimens were deposited in CEPEC's zoological collections and at the Federal University of Rio de Janeiro (CZUFRJ).

The eggs were found in the ground beside a fallen tree in a cacao plantation. They were ca. 15 cm from the surface and covered in soil and decomposed wood. They measured ca. 60 x 25 mm, and were soft to the touch and yellowish-white in color. The eggs were kept in the laboratory at room temperature (24°C) in a receptacle measuring 27 x 20 x 15 cm, containing 10 cm of vermiculite and covered with plastic mesh. The eggs were moistened with water every two days.

Hatching occurred on 9, 10, and 11 March. The animals first opened a small hole in the shell, just large enough to put their heads out (Figs. 2 and 3); this they did for several hours, appearing and retreating but without leaving the shell. During this process the animals displayed geotropic behavior; they turned towards the soil with the apparent intention of burying themselves (Figs. 2 and 3), but then withdrew once more into the shell. When they finally emerged, general examination showed them to have an egg-tooth.

The five hatchlings measured 150–170 mm total length (mean TL = 160.0 mm, SD = 0.707) and weighed 9.0–12.5 g (mean mass = 10.75 g, SD = 1.458).

The egg opened for species identification was well developed, and still had its yolk. The embryo had a conspicuous eye, proportionally larger than in the adult animal (Fig. 1); this was also the case in the young after hatching, and has been observed in *L. microcephalum* (Gans 1971. Bull. Am. Mus. Nat. Hist. 144:379–464).

The eggs were laid and hatched during the summer rainy season; the same occurs in *L. wuchereri*, also from southern Bahia (Zamprogno et al. 1993. Resumos III Congresso Latino-Americano de Herpetologia, Campiñas (Brazil), p. 36).

We thank Fundação Butantan for financial support and CNPq (Brazilian National Research Council) for providing our grants (CJ and MMA). We thank A. J. S. Argôlo and Alasdair G. Burman for comments and criticisms.

SERPENTES

BOTHROPS JARARACUSSU (Jararacussu). **PREY**. Few data are available on the feeding habits of *Bothrops jararacussu*, a large, heavy-bodied neotropical pitviper that reaches 2200 mm in total length (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. 425 pp.). This pitviper feed on rodents and frogs (Amaral 1976. Serpentes do Brasil, Melhoramentos, São Paulo. 246 pp.), and juveniles use caudal luring to attract insectivorous prey such as frogs (Sazima 1991. Copeia 1991:245–248). Herein, we report on a legless lizard eaten by this pitviper. An adult male *B. jararacussu* (865 mm SVL; 140 mm tail; 370 g mass), was caught by a plantation worker on 27 October 1995 near the Sítio Três Marias, Marechal Floriano, Espírito Santo, eastern Brazil (20°22'S, 40°42'W), elevation 680 m. Gut content analysis revealed a whole anguid lizard, *Ophiodes striatus*, (200 mm SVL; 195 mm tail, 32 g mass) and a small, partially digested rodent (estimated mass = 8 g), both ingested head first. The lizard showed no signs of digestion and represented 39.3% of the total length of the snake. The lizard's tail was complete and intact despite the reputation of *O. striatus* for ready autotomy of its tail into several pieces when handled (its Portuguese name is "cobra de vidro," literally "glass snake"). Examination of the lizard revealed a 4 mm wound on the lower left neck, perhaps due to the envenomation bite. The snake and its prey are in the Coleção Zoológica da Universidade Federal do Espírito Santo (ZUFES).

We thank I. Sazima for critically reading the manuscript, A. Regiani for providing the pitviper, and the PICDT/CAPES for a graduate fellowship to CZ.

PSEUDOBOODON LEMNISCATUS (Striped Ethiopian Mountain Snake) **REPRODUCTION and SIZE**. *Pseudoboodon* is a genus of medium-sized colubrids endemic to the highlands of Ethiopia and Eritrea. Until recently, there was believed to be only a single species, but Rasmussen and Largen (1992. Steenstrupia 18(3):65–80) revived a second species (*Pseudoboodon gascae*) from the synonymy of *P. lemniscatus* and described a third species, *P. boehmei*. There is no information on the reproduction of these two latter species, and the only information on reproduction in *P. lemniscatus* is that reported by Emmrich (1992. Walia 14:16–22), from Angenstein (pers comm.) who reported clutch sizes of 6–10 and hatchling sizes of 17–20 cm. I here present detailed data on reproduction in this species.

On 24 November 1991, a female *Pseudoboodon lemniscatus* (SVL 692 mm, total length [TL] 780 mm, mass 184 g) was collected crossing a road just after dark (1912 h, air temperature 17.5°C) in the grounds of the British Embassy, Addis Ababa (9°02'N 38°43'E, 2520 m). She was noticeably gravid and was housed in captivity. All food offered (small rodents and skinks) was refused and between 18–19 December 1991 she laid 12 eggs, between 1830 and 0600 h. She remained coiled around the eggs throughout the laying period, but left the eggs at 0700 h on 19 December and concealed herself under a tile in the cage. Her mass after laying was 130.8 g and the relative clutch mass = 0.319. The eggs were removed, separated into three groups (3, 4, and 5 eggs), and placed in damp soil in separate plastic tubs on the back of a refrigerator, where the temperature varied between 17–20°C. On 19 December the mean egg mass was 5.1 g (SD = 0.191, range = 4.8–5.3 g), mean length 30.25 mm (SD = 1.69, range = 28–34 mm), mean width 17.6 mm (SD = 0.616, range = 17–19 mm). During incubation, the tub with five eggs was knocked over and fell to the floor; all the eggs in it were then attacked by fungus and collapsed. On 8 April 1992 a small slit was seen in one of the remaining viable eggs. The eggs were weighed immediately; the mean mass of the seven remaining eggs was 8.77 g (SD = 0.958, range = 7.9–10.2 g), mean length 33.3 mm (SD = 1.43, range = 30.5–35.8 mm), mean width 22.5 mm (SD = 0.83, range = 21.7–23.8 mm). Between 8 and 16 April all seven eggs hatched. Mean total length of hatchlings was 188 mm (SD = 16.5, range = 172–225 mm), mean SVL 161 mm (SD = 16.3, range = 145–198), mean mass 2.28 g (SD = 0.678, range = 1.5–3.7 g). Incubation time thus varied between 111–119 days, but this may be unusually short due to the high incubation temperatures. In Addis Ababa soil temperatures at 30 cm vary from 10° to 17°C. All seven hatchlings were released in the grounds of the British Embassy. The female is still alive in the collection of David Brownlee (Newcastle, England) along with a male (collected 5 December 1991, also in the British Embassy, Addis Ababa; dimensions at capture: SVL 587 mm, TL 712 mm, mass 120 g).

The female produced a second clutch. Mating occurred during December 1993, a clutch of ten eggs were laid 28 January 1994; seven hatched on 16 May 1994 following 108 days of incubation at 29°C. Both snakes will be deposited in the collection of the British Museum (Natural History) upon death.

On 20 November 1993, a large female *P. lemniscatus*, TL 875, SVL 771 mm, mass 285.9 g, was killed at about 1600 h in the grounds of the British Embassy, Addis Ababa. Her oviducts contained 21 eggs measuring ca. 1.8 x 1.5 cm; the mass of all 21 eggs was 41 g (mean 1.95 g, eggs not weighed individually). The specimen and her eggs were placed in the collection of the Natural History Museum (Addis Ababa), specimen number NHAA (S) 1993.22.

On 6 June 1994, a hatchling *P. lemniscatus* (umbilical scar visible, TL 230 mm, SVL 205 mm) was collected under a rock at the Berek River, 30 km northeast of Addis Ababa (9°09'N, 38°57'E). This neonate was released after being photographed. Presuming this specimen hatched sometime during the previous month, we may conclude that under normal conditions, in central Shoa province (where Addis Ababa is located), egg-laying in *P. lemniscatus* occurs in December–January and hatchlings appear in May or June, coincident with the onset of the four-month rainy season, June–September.

The note below is being republished, as a corrected version, and originally appeared in volume 27, number 2 (June 1996).

SISTRURUS MILIARIUS BARBOURI (Dusky Pigmy Rattlesnake). **MAXIMUM SIZE.** In the spring of 1981, Mitchell Harris collected an adult male *Sistrurus miliarius barbouri* off Rt. 60 at a farm ca. 20 mi. west of Vero Beach, Indian River Co., Florida, USA. The specimen was given to the senior author, who maintained it in captivity from March 1981 until April 1993 (12 years, one month), when it died. We estimate the age of this snake to be ca. 20 years, because it was ca. 63.5 cm in length when caught in the wild. Its weight (on 23 July 1988) was 658 g. At its death, the specimen measured 73.8 cm total length (excluding rattle); in 1987, this snake had a live measurement of 80.3 cm in total length, a new maximum size for this race and the species. During the early part of its captivity, this specimen maintained only 2–3 rattle segments. However, despite repeated sheddings during the remainder of its life, these original segments wore down and the snake ceased adding any rattle segments. The specimen was preserved and deposited in the Florida State Museum of Natural History (UF-FSM 87590); color slides were deposited earlier (1987) at the Natural History Museum, The University of Kansas (KU Color Slides 7614-7615).

This specimen is the basis for the maximum size reported by Conant and Collins (1991. Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **EMMETT SNELLINGS, JR.**, 88 Mcteer Drive, St. Helena Island, South Carolina 29920, USA, and **JOSEPH T. COLLINS**, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.

THAMNOPHIS ELEGANS VAGRANS (Wandering Garter Snake). **PARALYSIS.** On 3 August 1993 at 1100 h, a female *Thamnophis elegans vagrans* (SVL 454 mm; TL 586 mm) was found in 0.5 m high grasses along the bank of Coyote Creek, 1.5 km E Guadalupita, Mora County, New Mexico, USA. Inspection of the snake exposed seven scars (three ventral, four dorsolateral) devoid of scales. The largest (9 x 7 mm) was located mid-dorsally at the apex of the vertebral column, 121 mm anterior of the vent.

During locomotion, the snake dragged the posterior portion of its body. Stimulus anterior and posterior to the injury verified that there was no detectable voluntary muscular response posterior to the site of the vertebral injury (26.7% of SVL; 43.2% of TL). Involuntary response was observed when scratching of the skin induced contraction of tail muscles to the point where the tail would wrap around a finger.

Radiographs of the snake indicate the spinal column was severed and healed with a lateral misalignment (Fig. 1). The misalignment supports the assessment that the spinal injury caused paralysis. Since capture, the snake has fed regularly and grown to 513 mm SVL (656 mm TL) by November 1995. Defecation regularly follows feeding, although atypical bulging occurs both anterior and posterior to the spinal column injury, and cloacal control seems to be lacking.

Between 0800 and 1800 h on 20 August (17 d after capture), the female gave birth to three young measuring 103, 114, and 119 mm SVL. The smallest newborn died on 14 September at 106 mm without feeding, whereas the two larger individuals died on 9 December 1993 (155 SVL) and 7 February 1994 (183 SVL). Normal size ranges for *T. elegans* at birth were reported as 180–230 mm by Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.) and 167–215 mm by Wright and Wright (1994. Handbook of Snakes of the United States and Canada. Vol. II. Comstock Publ. Assoc., Ithaca, New York. 565–1106 pp.), with the smallest recorded as 122 mm (Wright and Wright, *op. cit.*). Litter sizes range from 4–19 (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians, 2nd ed. Houghton Mifflin Co., Boston, Massachusetts 336 pp.) and 4–14 (mean 9.1) (Fitch 1985. Univ. Kansas, Mus. Nat. Hist., Misc. Publ. 76:1–76). Whether the spinal injury was related to the low litter number, small size of the young at birth, and their high mortality is speculative.

Scientific permit to SK was provided by the New Mexico Department of Game and Fish. We acknowledge Tim E. Robinson for the radiographs. Thanks to Robert D. Owen, Llewellyn D. Densmore, and Lorinda L. Gordon for reviewing the manuscript.

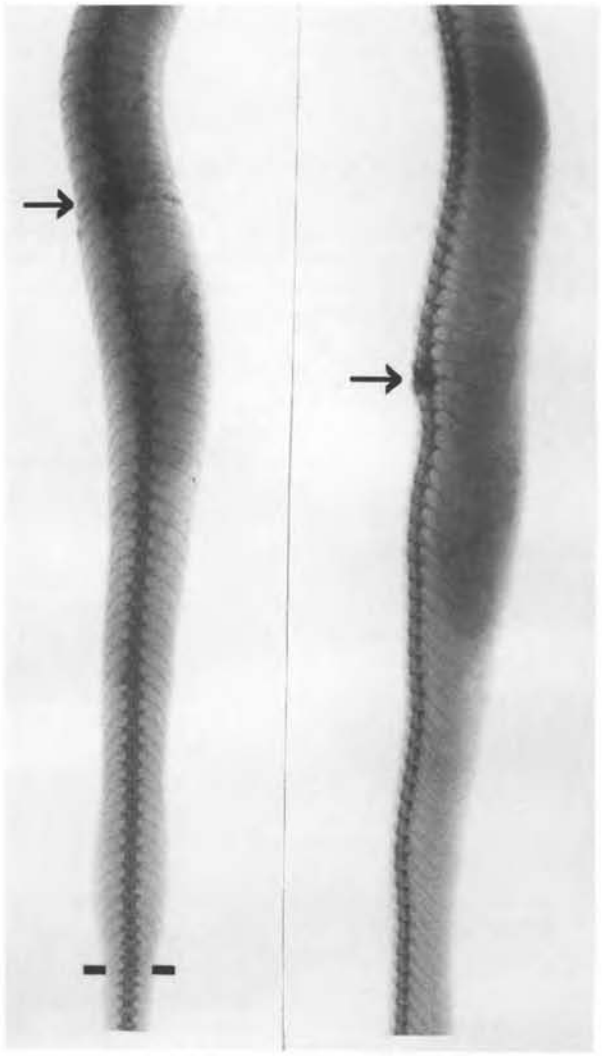

FIG. 1. Radiographs of female *Thamnophis elegans vagrans* indicating position of vertebral injury between the 44th and 45th precaudal vertebrae (arrows). The lateral view (right) shows a slight downward tilt across the fused vertebrae. Bars denote approximate position of vent (left, dorsal view).

Submitted by **STEPHEN KASPER**, Department of Biological Sciences and The Museum, Texas Tech University, Lubbock, Texas 79409, USA, and **STEPHANIE N. KASPER**, 4512 49th St., Lubbock, Texas 79414, USA.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19:1–41; for México as it appears in Liner, 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*. Herp. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: Joseph T. Collins (USA & Canadian records only), Museum of Natural History—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA; Jerry D. Johnson (México and Central America, including the Caribbean islands), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA; Hidetoshi Ota (all Old World records), Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; or Gustavo J. Scrocchi (South American records), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Submissions by e-mail are encouraged where possible**. Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Marques, O. A. V., and G. Puorto. 1996. Geographic Distribution. *Chironius laevicollis*. Herpetol. Rev. 27:212.

CAUDATA

AMBYSTOMA LATERALE (Blue-spotted Salamander). USA: WISCONSIN: Menominee Co: ca. 30 m E jct. of Rt. VV and Sunrise Road, Center of Sec 23, T28N, R16E. 23 September 1996. Gary S. Casper. Verified by Robert W. Henderson. MPM Herpetology Collection 27982–983. New county record, filling gap in expected distribution (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Pub. Mus. 87 pp.). Two specimens found under logs at shore of small pond in oak woodland.

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA.

AMPHIUMA MEANS (Two-toed Amphiuma). USA: FLORIDA: Franklin Co: St. Vincent Island, on Rattlesnake Slough Road north of Oyster Pond. 6 October 1995. Thomas E. Lewis. One specimen photographed, UF 104084. Verified by David Auth. Found alive in a tire rut, apparently after having been washed out of Oyster Pond when a water control structure failed during Hurricane Opal on 5 October 1995. First record for any Gulf Coast barrier island (Blaney 1971, Herpetologica 27(4):406–430).

Submitted by **D. BRUCE MEANS** and **THOMAS E. LEWIS**, Coastal Plains Institute, 1313 North Duval Street, Tallahassee, Florida 32303, USA, and St. Vincent National Wildlife Refuge, P.O. Box 447, Apalachicola, Florida 32329, USA.

NOTOPHTHALMUS MERIDIONALIS (Black-Spotted Newt). USA: TEXAS: McMullen Co: 27°37'48"N, 97°18'36"W. Adult male crossing Texas Rt. 16, S of Tilden, 15 m N Nueces River bridge in the rain at 2140 h. 31 August 1995. Travis W. Taggart and Richard Anderson. KU Color Slide 11223. Verified by James R. Dixon. County record; lends support for the records cited as questionable by Dixon (1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.) for Duval (USNM 15683, 14740) and Bexar (USNM 45400–45423) counties. Dixon (pers. comm.) never examined these specimens and they were not included in his map on the basis of their suspect locality.

Submitted by **TRAVIS W. TAGGART**, Department of Biological Sciences-SLU 736, Southeastern Louisiana University, Hammond, Louisiana 70402, USA.

ANURA

ASCAPHUS TRUEI (Tailed Frog). USA: OREGON: Wasco Co: Warm Springs Reservation, Wilson Creek, 3.7 km S Rt. 26, NE 1/16 of SW 1/4, Sec.36, T5S, R9E (UTM N4993850m, E609080m) upstream from jct. of road and Wilson Creek; unnamed tributary of the South Fork of the Warm Springs River, 3 km E of the Pacific Crest Trail, Center of the NE 1/4, Sec. 32, T7S, R9E (UTM N4975000m, E603760). 8 September 1995. Stacy N. Smith. Oregon State University Herpetological Collection Photographic Records (OS 11335–337). All verified by R. Bruce Bury. Three adults found at the South Fork of the Warm Springs River site, two adults also captured at this site in 1994. Four tadpoles and one adult captured at the Wilson Creek site. Three tadpoles and one adult also were captured 1.5 km downstream from the road crossing in 1994. First county records; Wilson Creek site is ca. 24 km SW of Hood River County locality, and the South Fork of the Warm Springs River site is ca. 14 km NE of the Marion County locality (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Press of Idaho, Moscow. 332 pp.).

Submitted by **STACY N. SMITH**, Environmental Services Northwest, 2134 Minute Court, Stone Mountain, Georgia 30087, USA.

BUFO CALIFORNICUS (Arroyo Toad). MÉXICO: BAJA CALIFORNIA: Arroyo San Simon, ca. 16 km SE San Quintin, 30°27'00"N, 115°51'00"W. 18 March 1995. Eric W. A. Gergus. LACM Color Slide PC1316. Verified by Brian K. Sullivan. At least seven males were seen calling along the margins of the arroyo. Extends range ca. 38 km S of nearest record at Río Santo Domingo (Price and Sullivan 1988, Cat. Amer. Amphib. Rept. 415:1–3).

Submitted by **ERIC W. A. GERGUS**, Department of Zoology, Arizona State University, Tempe, Arizona 85287, USA, **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515, USA, and **KENT BEAMAN**, 1159 Iowa Avenue, Suites E and F, Riverside, California 92507, USA.

BUFO VALLICEPS (Gulf Coast Toad) USA: TEXAS: HARRISON CO: Karnack, 5.6 km E main entrance of Longhorn Army Ammunition Plant, near Harrison Bayou. 30 April 1996. Bradley C. Autrey and Ryan Daniel. Verified by Fred L. Rainwater. Stephen F. Austin State University Vertebrate Museum (SFAVM 4891). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). Individual was collected from a funnel trap located in a mesic hardwood area on the Longhorn Army Ammunition Plant.

Submitted by **ROBERT R. FLEET** and **BRADLEY C. AUTREY**, Department of Biology, Stephen F. Austin State University, Nacogdoches, Texas 75962, USA.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad) USA: COLORADO: LAS ANIMAS CO: pond on unnamed creek, 2.0 air mi due W of Las Animas/Baca County line, 0.9 air mi due S jct W Carrizo Creek. 3 June 1996. UNC-MNH Photographs 18–19. Verified by Hobart M. Smith and David Chiszar. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **SCOTT BOBACK**, **ENOCH BERGMAN**, **CHAD MONTGOMERY**, **JUSTIN HOBERT**, **BEN HILL**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: TEXAS: HALE CO: 17.7 km W Petersburg. 2 June 1996. Ann M. Anderson, Warren C. Conway, and David A. Haukos. Museum of Texas Tech University (TTU-R-11633). Verified by Richard Monk. County record; several adult males were heard and seen calling at 0100 h in a flooded playa wetland. One individual was captured in dense vegetation. Extends range of the species northwest (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.) Fills hiatus in current known distribution of species—Swisher County to the north, Floyd County to the east, and Crosby and Lubbock counties to the south.

Submitted by **ANN M. ANDERSON**, **WARREN C. CONWAY**, and **DAVID A. HAUKOS**, Range and Wildlife Department, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79409, USA.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: TEXAS: HOCKLEY CO: 8.1 km N Smyer. 2 June 1996. Ann M. Anderson and David A. Haukos. Museum of Texas Tech University (TTU-R-11634). Verified by Richard Monk. County record; several adult males were heard and seen calling after sunset in a flooded playa wetland. One individual male was captured by hand in dense vegetation. Extends range of the species northwest (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.)

Submitted by **ANN A. ANDERSON** and **DAVID A. HAUKOS**, Range and Wildlife Department, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79404, USA.

HYALINOBATRACHIUM CHIRRIPOI (Suretka Glass Frog). PANAMÁ: PROVINCIA DE DARIEN: DISTRITO DE PINOGANA: Parque Nacional Darién, Estación Pirre, Río Peresénico, 8°01'09"N, 77°43'57"W, elev. 90 m. 24 August 1994. Roberto Ibáñez D. Círculo Herpetológico de Panamá (CH 4048). Verified by Jay M. Savage. New country record. Although Frost ([as *Centrolenella*]1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.) and Auth (1994, Smithson. Herpetol. Info. Ser. 98:1–59) indicated that it was distributed from Costa Rica to Colombia, and Villa et al. ([as *Centrolenella*] 1988, Middle American Herpetology. Univ. Missouri Press, Columbia. 131 pp.) erroneously showed it as present in Panamá, this species was only known from localities in Costa Rica and Colombia ([as *Centrolenella*] Starrett and Savage 1973, Bull. So. California Acad. Sci. 72:57–78; [as *Centrolenella*] Hayes and Starrett 1980, Bull. So. California Acad. Sci. 79:89–96). Partially fills the gap between previous records and confirms its presence in Panamá.

Submitted by **ROBERTO IBÁÑEZ D.**, Smithsonian Tropical Research Institute, Apartado 2072, Balboa, Republica de Panamá, and **CESAR A. JARAMILLO**, Círculo Herpetológico de Panamá, Apartado 10762, Estafeta Universitaria, Panamá, Republica de Panamá.

HYLA CINEREA (Green Treefrog). USA: TENNESSEE: DYER CO: Chic (Tennessee) topographic quadrangle, Moss Island State Wildlife Management Area, ca. 1 km SW of jct. of Big Levee and Moss Island roads (35°57'23"N, 89°37'58"W), 76 m elev. August 1994. Carl Wirwa. Austin Peay State University Museum of Zoology (APSU Photograph Collection 05423). Verified by A. Floyd Scott. Adult captured in open area among patches of bottomland hardwoods, photographed and released. New county record (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee. Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **ALAN PETERSON** and **CARL WIRWA**, Tennessee Wildlife Resources Agency, Box 55 State Office Building, 225 Dr. Martin Luther King Drive, Jackson, Tennessee 38301, USA.

HYLA GRATIOSA (Barking Treefrog). USA: TENNESSEE: CHESTER CO: Henderson (Tennessee) topographic quadrangle, 2.5 mi S of Henderson at 1395 Memory Lane (35°24'04"N, 88°38'06"W), 141 m elev. 4 September 1993. Amy Peterson and Christie Peterson. Austin Peay State University Museum of Zoology Photograph Collection (APSU 05419). Verified by A. Floyd Scott. Adult captured on inside wall of house. A second specimen was captured by Alan Peterson thirteen months later crossing Memory Lane ca. 100 m N of the first capture site. New county record (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee. Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **ALAN PETERSON**, Tennessee Wildlife Resources Agency, and **JOHN KOONS**, Department of Natural and Physical Sciences, Jackson State Community College, Jackson, Tennessee 38301-3797, USA.

PHYLLOMEDUSA BICOLOR (Giant Monkey Frog): BOLIVIA: BENI: PROVINCIA VACA DIEZ: between Villa Vella and Cachuela Esperanza at ca. 5 km from Villa Vella. 20 February 1996. F. Guerra Serrudo and E. Perez Limache. Coleccion Boliviana de Fauna La Paz (CBF 2446-48). Verified by A. Schlüter. First record for Bolivia.

Submitted by **STEFFEN REICHLE**, Langwiesenstr. 26, D-70771 Leinfelden-Echterdingen, Germany; **FERNANDO GUERRA SERRUDO** and **EDDY PEREZ LIMACHE**, Coleccion Boliviana de Fauna, Casilla 8706, La Paz, Bolivia.

PSEUDACRIS TRISERIATA TRISERIATA (Western Chorus Frog). USA: WISCONSIN: ONEIDA CO: 0.25 mi SE jct. of Rt. G and Rt. 8/47, SW 1/4 of SE 1/4 of SW 1/4 Sec. 8, T36N, R9E. 2, 8, and 18 May 1996. Ron Eckstein. MPM Herpetology Audio Tape Collection (cat. no. pending). Verified by Robert W. Henderson. New county record (Casper 1996, Geographic Distributions of the

Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Wisconsin. 87 pp.); an additional record for northeast Wisconsin, where this species is rare and local.

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA.

SCAPHIOPUS COUCHII (Couch's Spadefoot). USA: NEW MEXICO: Cibola Co: Laguna Reservation, 0.4 km N and 1.6 km W of Mesita (SE 1/4 Sec. 11, T9N, R5W). 15 June 1996. S. E. Carr. KU Photograph Accession 6562. Verified by C. W. Painter. First record for county; extends range ca. 35 km NW from Valencia County in the Rio Puerco/Rio Salado drainage basin (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xx + 431 pp.).

Submitted by **STACEY E. CARR**, Department of Natural Resources, Pueblo of Laguna, P.O. Box 194, Old Laguna, New Mexico 87026, USA; and **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

TESTUDINES

CHRYSEMYS PICTA BELLII (Western Painted Turtle) USA: COLORADO: Bent Co: DOR, Rt 50, 0.9 mi W jct of County Road 28. 7 October 1996. UNC-MNH 213. Verified by Hobart M. Smith and David Chiszar. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **ENOCH BERGMAN**, **BEN HILL**, **CHAD MONTGOMERY**, **JUSTIN HOBERT**, **SCOTT BOBACK,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

GRAPTEMYS GEOGRAPHICA (Common Map Turtle). USA: WISCONSIN: Shawano Co: 0.75 miles west of Morgan Road on Rt. A, W1/2 Sec. 32, T28N, R14E. 20 May 1996. Greg Bunker. MPM Herpetology Collection 27978. Verified by Robert W. Henderson. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Wisconsin. 87 pp.) Adult female killed on road near small tributary of the Red River (Wolf River watershed). Extends range ca. 22 km N of nearest locality in northern Waupaca County, also in Wolf River watershed (Vogt 1981, Natural History of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Wisconsin. 205 pp.)

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA.

GRAPTEMYS KOHNII (Mississippi Map Turtle). USA: OKLAHOMA: Choctaw Co: Hugo Wildlife Management Area, NE 1/4, SE 1/4, Sec 13, T5S, R17E. 21 June 1994. David G. Smith. Oklahoma Museum of Natural History (OMNH 35453). Verified by Laurie J. Vitt. Adult collected in a mud puddle on a gravel road (old Oklahoma Rt. 93) ca. 4 km SE of One Creek entrance to Hugo Wildlife Management Area during midday. New county record (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press, Norman. 370 pp.).

Submitted by **DAVID G. SMITH**, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, USA.

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow Mud Turtle). USA: NEW MEXICO: Socorro Co: Bosque del Apache National Wildlife Refuge, Unit 11 pond, 2.4 km NNE Refuge headquarters. 11 July 1996. J. N. Stuart. University of New Mexico Museum of Southwestern Biology (MSB) 60412. Verified by C. W. Painter. First record for county; other confirmed records for Rio Grande Valley are from downstream of Caballo Dam (Dona Ana and Sierra counties) and an introduction in Sandoval County (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xx + 431 pp.). Specimen may be introduced because no other *K. flavescens* have been found at Refuge despite extensive trapping. Collected under U.S. Fish and Wildlife Service Special Use Permit No. 73627.

Submitted by **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: INDIANA: Union Co: Whitewater State Park: extreme NE margin of Whitewater Lake, 39°37'23"N, 84°57'37"W. 9 August 1996. Matt Rail and Art Reber. UF 104530. Verified by David L. Auth. Specimen caught on trotline in 0.75 m of water. New county record (Minton 1997, Amphibians and Reptiles of Indiana. Second ed. Indiana Acad. Sci., Indianapolis. In press).

Submitted by **CAMERON A. YOUNG** and **JOHN B. IVERSON**, Joseph Moore Museum, Department of Biology, Earlham College, National Road West, Richmond, Indiana 47374, USA.

TRACHEMYS SCRIPTA SCRIPTA (Yellowbelly Slider). USA: VIRGINIA: Gloucester Co: 1.6 km E White Marsh, West Branch of Severn River. 24 June 1996. John A. Musick. USNM 509512. Verified by George R. Zug. Adult, non-gravid female (262 mm carapace length, 245 mm plastron length, 2581 g body mass) found adjacent to water-filled ditch on road. Extension of eastern part of range across York River, 16 km north of nearest record in City of Newport News. First record for the middle peninsula of Virginia and Gloucester County (Mitchell 1994, The Reptiles of Virginia. Smithsonian Inst. Press. 352 pp.).

Submitted by **JOSEPH C. MITCHELL**, Department of Biology and School of Continuing Studies, University of Richmond, Richmond, Virginia 23173, USA, and **JOHN A. MUSICK**, Virginia Institute of Marine Science, P.O. Box 1346, Gloucester Point, Virginia 23062, USA.

SAURIA

ANOLIS CAROLINENSIS CAROLINENSIS (Northern Green Anole) USA: TEXAS: Ellis Co: Bristol. 11 October 1996. Debbie M. Arnold. Navaro College 1996.10.11.1L. Verified by Tom Vance. New county record; partly fills hiatus of its western range. (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.; Vance 1992, Bull. Maryland Herpetol. Soc. 27(2):48–89; Vermersch 1992, Lizards and Turtles of South-Central Texas. Eakin Press, Austin. 170 pp.; Hibbitts and Hibbitts 1994, Herpetol. Rev. 25(1):35–36).

Submitted by **DEBBIE M. ARNOLD**, 403 Old Walnut, Ennis, Texas 75119, USA.

CROTAPHYTUS BICINCTORES (Mojave Black-collared Lizard). USA: ARIZONA: Maricopa Co: White Tank Mountains, NE end, access off of Bell Road. 16 April 1996. Bradford D. Hollingsworth and Erik W. A. Gergus. TNHC 53903. Verified by Jimmy A. McGuire. The White Tank Mountains lie 40 km west of

Phoenix, north of the Gila River, and represent the easternmost distribution of *C. bicinctores* in Maricopa County. The nearest distributional records include Wickenburg (UIMNH 74801) and the Gila Bend Mountains, a distance of 40 km to the NW and 55 km to the SSW, respectively (McGuire 1996, Bull. Carnegie Mus. Nat. Hist. 32:1–143).

Submitted by **BRADFORD D. HOLLINGSWORTH**, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA, and **ERIK W. A. GERGUS**, Department of Zoology, Arizona State University, Tempe, Arizona 85287, USA.

CROTAPHYTUS NEBRIUS (Sonoran Collared Lizard). USA: ARIZONA: PINAL CO: Sacaton Mountains, W of Rt. 387, access off of Hopi Road. 14 April 1996. Bradford D. Hollingsworth and Erik W. A. Gergus. TNHC 53904. Verified by Jimmy A. McGuire. First confirmed county record; specimen was collected on the W side of the Sacaton Mountains, which are divided by Rts. 10 and 387. Nearest distribution records include the Silver Bell Mountains (SDSNH 68648–49) and 20 mi SW of Phoenix in the Sierra Estrella (KU 14860), a distance of 70 km to the SSE and 55 km to the NW, respectively (McGuire 1996, Bull. Carnegie Mus. Nat. Hist. 32:1–143).

Submitted by **BRADFORD D. HOLLINGSWORTH**, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA, and **ERIK W. A. GERGUS**, Department of Zoology, Arizona State University, Tempe, Arizona 85287, USA.

EUMECES FASCIATUS (Five-lined Skink). USA: ILLINOIS: MCHENRY CO: Northern Roofing Company, Rt. 47, Huntley. 11 September 1996. Michael Abmbrogio. The Museum of Northern Illinois University (HDW-NIU 1621). Verified by Harlan Walley. Specimen found basking near skid of roofing insulation. New county record; fills gap between Cook and Lake counties to the east (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: GEORGIA: CHATHAM CO: Savannah historic district, Forsythe Park/Whittaker Street, 3.7 mi (6.2 km) W of Savannah River (Georgia-South Carolina state line). 29 September 1996. Michael G. Frick. Savannah Science Museum (SSM 96.13759–96.13760). Verified by John B. Jensen. Specimens caught in ivy on brick wall. New county record (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.; Williamson and Moulis 1994, Distribution of Reptiles and Amphibians in Georgia. Vols. 1–2. Savannah Science Museum Special Publication No. 3. Savannah Science Museum, Georgia. 912 pp.); probably an established population since individuals of different size classes have been observed.

Submitted by **MICHAEL G. FRICK**, Savannah Science Museum, 4405 Paulsen Street, Savannah, Georgia 31405, USA.

KENTROPIX STRIATA (Striped Kentropyx) VENEZUELA: ARAGUA: Maracay, El Limón, Estación de Fuana, 500 m. 25 November 1988. Ramón Rivero. Museo de la Estación Biológica de Rancho Grande, Maracay (EBRG 2308); ESTADO GUARICO: San Juan de los Morros, Las Acequias, 480 m. 13 April 1996. Marco Natera. EBRG 3255, 3256. Verified by Luis Fernando Navarrete. First record for the states of Aragua and Guárico, and northernmost localities in the Central Region of Venezuela [Gallenger and Dixon 1992, Boll. Mus. Reg. Sci. Nat. Torino 10(1):125–171; Avila-Pires 1995, Lizards of Brasilian Amazonia (Reptiles: Squamata). Zool. Verh. 299:529–535].

Submitted by **JESUS MANZAMILLA**, Museo del Instituto de Zoología Agrícola, Universidad Central de Venezuela, Apartado Postal 4579, Maracay 2101-A, Aragua, Venezuela, **RAMON RIVERO**, Museo de la Estación Biológica de Rancho Grande, El Limón, Aragua, Venezuela, and **MARCO NATRA**, Universidad Rómulo Gallegos, San Juan de los Morros, Guárico, Venezuela.

LIOLAEMUS PSEUDOANOMALUS (Tree Iguana). ARGENTINA: SAN JUAN: DEPARTMENT ULLUM: 12 km W San City on Loma de las Tapias Hill (31°29'S, 68°39'W). April 1995. Juan Carlos Acosta. March 1996. Victor Contreras. Herpetological Collection, Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina (IMCN-UNSJ 108 [juv] and 109 [hatchlings]). Verified by Luciano Javier Avila. Extends range ca. 67 km from Médanos Grandes, Department Caucete (Cei 1986, Mon. IV Mus. Reg. Sci. Nat. Torino. 527 pp.).

Submitted by **JUAN CARLOS ACOSTA** and **FERNANDO MURÚA**, Instituto y Museo de Ciencias Naturales, Universdad Nacional de San Juan, Avenida Libertador (Oeste) N° 315, C.P. 5400, San Juan, Argentina.

OPHIODES YACUPOI (Mboi-pepé, Yacupoi Worm Lizard) ARGENTINA: CORRIENTES, DEPARTMENT MBURUCUYÁ: Campo Nalda (28°08'S, 58°21'W). 16 October 1995. Enrique Laffont. Universidad Nacional del N.E. (UNNEC 04848); Rt. 86 W Mburucuyá (28°03'S, 58°11'W). 30 November 1995. Ruben Maletti and Carlos Alberto Saibene. UNNEC 04880. Both verified by Blanca Beatríz Alvarez. First record for province. Other Argentine provinces where species has been recorded are: Misiones (Gallardo 1966, Rev. Mus. Arg. de Cs. Nat. Zool. 9[6]:123–146) and Entre Ríos (Genise 1983, Bol. As. Herp. Arg. 1[3]:18). Cited also for Uruguay and Brazil (Peters and Donoso Barros 1970, Bull. U.S. Natl. Mus. 297:1–293).

Submitted by **SILVANA BEATRIZ MONTANELLI**, Parque Nacional Mburucuyá, C.C. N° 1 (3427) Mburucuyá, Corrientes, Argentina, and **JUAN CARLOS CHEBEZ**, Delegación Técnica Regional NEA, Avenida Victoria Aguirre 66 (3370) Pto. Iguazú, Misiones, Argentina.

PHRYNOSOMA MODESTUM (Roundtail Horned Lizard). USA: ARIZONA: GILA CO: Mohave Point, San Carlos Lake, San Carlos Indian Reservation, 9 km (airline) NE of Coolidge Dam. 1 April 1989. Amy Lynn Mayne. Arizona State University Photo Collection (ASU PC 001–002). Verified by M. J. Fouquette, Jr. New county record; extends range 48 km (airline) NW of Fort Thomas (Tanner 1958, Herpetologica 14:195).

Submitted by **PETER J. MAYNE**, 17510 North 85th Lane, Peoria, Arizona 85382, USA.

PHYLLODACTYLUS XANTI (Cape Leaf-toed Gecko). MÉXICO: BAJA CALIFORNIA SUR: Isla Pardo, one of five small islands in a group collectively known as Islas Los Candeleros located SW of Isla Danzante in the vicinity of Loreto (Crumpton 1991, Baja Explorer: Topographic Atlas Directory. ALTI Publishing, La Jolla, California; Williams 1988, Baja Boater's Guide: Volume II—Sea of Cortéz. H. J. Williams Publications, Sausalito, California). 22 March 1996. L. Lee Grismer, Bradford D. Hollingsworth, Humberto Wong, and Michael R. Cryder. La Sierra University Photographic Collection (LSUPC L3026). Verified by Lester E. Harris. First record for Isla Pardo (Murphy and Ottley 1984, Ann. Carnegie Mus. Nat. Hist. 53:207–230). The

specimen was found during the day beneath a pile of rocks on the cobblestone beach.

Submitted by **MICHAEL R. CRYDER**, Department of Natural Sciences, Loma Linda University, Loma Linda, California, 92350, and Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, **BRADFORD D. HOLLINGSWORTH**, Department of Natural Sciences, Loma Linda University, Loma Linda, California, 92350, and Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, and **HUMBERTO WONG**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

SAUROMALUS ATER ATER (Espiritu Santo Chuckwalla). MÉXICO: BAJA CALIFORNIA SUR: Isla Pardo, one of five small islands in a group collectively known as Islas Los Candeleros, located SW of Isla Danzante in the vicinity of Loreto. Isla Pardo is the southernmost island found immediately across from Punta Candeleros (Williams 1988, Baja Boater's Guide: Volume II—Sea of Cortéz. H. J. Williams Publications, Sausalito, California). 22 March 1996. Bradford D. Hollingsworth, L. Lee Grismer, and Michael R. Cryder. La Sierra University Photographic Collection (LSUPC L3025). Verified by Lester E. Harris. First record for Isla Pardo, an island not previously mentioned in the herpetological literature (Murphy and Ottley 1984, Ann. Carnegie Mus. Nat. Hist. 53:207–230). Specimen is referred to *S. ater ater* based on its geographic proximity to the closest insular population of *Sauromalus* (Murphy and Ottley 1984, op. cit.) and was photographed and released on site.

Submitted by **BRADFORD D. HOLLINGSWORTH**, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA, **L. LEE GRISMER** and **HUMBERTO WONG**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, and **MICHAEL R. CRYDER**, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA

UROSAURUS NIGRICAUDUS (Blacktail Brush Lizard). MÉXICO: BAJA CALIFORNIA SUR: Islas Las Islitas, Las Tijeras and Pardo, three of five islands known collectively as Islas Los Candeleros located SW of Isla Danzante in the vicinity of Loreto (Crumpton 1991, Baja Explorer: Topographic Atlas Directory. ALTI Publishing, La Jolla, California; Williams 1988, Baja Boater's Guide: Volume II—Sea of Cortéz. H. J. Williams Publications, Sausalito, California). 22 March 1996. L. Lee Grismer, Bradford D. Hollingsworth, Michael R. Cryder, and Humberto Wong. La Sierra University Photographic Collection (LSUPC L3022-24). Verified by Lester E. Harris. Specimens from all three islands were captured, photographed, and released on site. These are three new insular records for *U. nigricaudus* as well as three new islands not mentioned previously in the herpetological literature (Murphy and Ottley 1984, Ann. Carnegie Mus. Nat. Hist. 53:207–230). This constitutes one of four new herpetological records for Isla Pardo (Cryder et al. 1997, Herpetol. Rev. 28:50–51; Grismer et al. 1997, Herpetol. Rev. 28:51; Hollingsworth et al. 1997, Herpetol. Rev. 28:51), the largest (0.06 km^2) of the five islands.

Submitted by **HUMBERTO WONG** and **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, and **BRADFORD D. HOLLINGSWORTH** and **MICHAEL R. CRYDER**, Department of Natural Sciences, Loma Linda University, Loma Linda, California, 92350 USA and Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

SERPENTES

ATRACTUS TAENIATUS (Ground Snake) ARGENTINA: CORRIENTES: DEPARTAMENTO SANTO TOME: Santo Tome. (28°33'S, 56°02'W). 10 July 1995. L. Shoijet. Coleccion Herpetologica de la Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 04979, female). Verified by A. Giraudo. First province record (mentioned as probable by Williams and Francini 1991, Bol. Mus. Reg. Sci. Nat. Torino 9(1):61–62).

Submitted by **LAURA RAQUEL REY**, Centro Regional Productor de Suero Antiofidico, Departamento de Herpetologia, Ministerio de Agricultura, Ganaderia, Industria y Comercio, Avenida Costanera No. 255, (3400) Corrientes, Argentina, and **MARIA LUISA LIONS** Anatomia Comparada, Facultad de Ciencias Exactas y Naturales, UNNE, 9 Julio 1449, (3400) Corrientes, Argentina.

CHILOMENISCUS CINCTUS (Banded Sand Snake). MÉXICO: SONORA: Isla Tiburón, Arroyo Sausál, SW side of island. 31 October 1958. R. Felger. UAZ 23194. Verified by Peter A. Holm. A second specimen was collected by R. Felger on 1 May 1964 from the same locality (UAZ 23195). *Chilomeniscus stramineus* has also been reported from Isla Tiburón (Grismer 1994, Herpetol. Nat. Hist. 2(2):17–40), and is substantiated by three specimens of *C. stramineus* mislabeled as *C. cinctus* from El Tecomate on the northern end of Isla Tiburón (USNM 222051–53). In addition to Isla Cerralvo, this is the second reported instance where two species of *Chilomeniscus* occur on the same island (Powers and Banta 1974, J. Herpetol. 8:386–387).

Submitted by **HUMBERTO WONG**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

CROTALUS ENYO ENYO (Baja California Rattlesnake). MÉXICO: BAJA CALIFORNIA SUR: Isla Pardo, one of five small islands in a group collectively known as Islas Los Candeleros, located SW of Isla Danzante, 13.5 km south of Puerto Escondido (Crumpton 1991, Baja Explorer: Topographic Atlas Directory. ALTI Publishing, La Jolla, California; Williams 1988, Baja Boater's Guide: Volume II—Sea of Cortéz. H. J. Williams Publications, Sausalito, California). 22 March 1996. L. Lee Grismer, Bradford D. Hollingsworth, Humberto Wong, and Michael R. Cryder. La Sierra University Photographic Collection (LSUPC S757-62). Verified by Lester E. Harris. First record from Isla Pardo, an island not previously mentioned in the herpetological literature (Murphy and Ottley 1984, Ann. Carnegie Mus. Nat. Hist. 53:207–230). Specimen was found beneath rocks on crest of the island (ca. 100 m), and was photographed and released on site. It is noteworthy that this was one of four species of reptiles (see Cryder et al.; Hollingsworth et al.; Wong et al.; this volume) discovered on this extremely small island (ca. 0.06 km^2).

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA; **BRADFORD D. HOLLINGSWORTH**, and **MICHAEL R. CRYDER**, Department of Natural Sciences, Loma Linda University, Loma Linda, California, 92350 USA and Department of Biology, La Sierra University, Riverside, California 92515-8247 USA, and **HUMBERTO WONG**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: NEW MEXICO: OTERO CO: N of Co. Rd. F-1, 1/2 km (air) W Pate Windmill (NE 1/4 Sec. 25, T25S, R12E), ca. 1500 m elev. 28 July 1996. Deborah Gordon. Laboratory for Environmental Biology, University of Texas at El Paso (UTEP 16438). Verified by C. S. Lieb.

Male, 425 mm SVL, 105 mm tail; 13.5 g weight; "ringless" pattern morph *of D. p. regalis* collected under a fallen yucca in open grassland. The specimen is apparently the second record for Otero County, and from a locality about 65 air km equidistant from all others in New Mexico (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico, Univ. New Mexico Press, Albuquerque, xix + 431pp).

Submitted by **DEBORAH J. GORDON**, Laboratory for Environmental Biology and Department of Biological Sciences, Universtiy of Texas at El Paso, El Paso, Texas 79968-0519, USA.

HETERODON NASICUS NASICUS (Plains Hognose Snake). USA: NEW MEXICO: CIBOLA CO: Laguna Reservation, 3.6 km N and 3.2 km E of Laguna, T10N, R5W, Sec. 27. 23 September 1996. S. E. Carr. University of New Mexico Museum of Southwestern Biology (MSB 60414). Verified by C. W. Painter. First record for county; extends range ca. 50 km W from Rio Grande Valley, Bernalillo County (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xx + 431 pp.).

Submitted by **STACEY E. CARR**, Department of Natural Resources, Pueblo of Laguna, P.O. Box 194, Old Laguna, New Mexico 87026, USA; and **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

HYDROPS TRIANGULARIS (Triangle Water Snake). BRAZIL: STATE OF PIAUÍ: Ribeiro Goncalves (7°32'S 45°14'W). Museu de História Natural Capão da Imbuia, Curitiba (MHNCI 2566). Verified by Sérgio A. A. Morato. Male (SVL 399 mm, tail 107 mm, dorsal rows 17-15-15, 156 ventrals, 58 subcaudals); represents first record for state of Paiuî and the River Parnaíba basin, and also is the most eastern record for the species.

Submitted by **RUBENS N. YUKI**, Universidade Federal do Paraná and Museu Paraense Emílio Goeldi, Postal Box 399, Belém, Para, Brazil, CEP 66017-970. E-mail: yuki@museu. goeldi.br

LAMPROPELTIS GETULA NIGRA (Black Kingsnake). USA: INDIANA: DECATUR CO: DOR 0.64 km N Decatur-Jennings County line on Ind. Rt. 3. 18 May 1996. Cameron A. Young. UF 104038. Verified by David L. Auth. New county record; ca. 18 km range extension NE from previous records (Minton 1997, Amphibians and Reptiles of Indiana. Second ed. Indiana Acad. Sci., Indianapolis. In press). This record corroborated by two more DOR *L. g. nigra* found on the same day: Jennings Co: 1.1 km S Sand Creek on Indiana Rt. 3, (UF 104037) and 1.1 km N Sand Creek on Indiana Rt. 3 (carcass not saved but verified by John B. Iverson).

Submitted by **CAMERON A. YOUNG** and **JOHN B. IVERSON**, Joseph Moore Museum, Department of Biology, Earlham College, National Road West, Richmond, Indiana 47374, USA.

LAMPROPELTIS TRIANGULUM GENTILIS (Central Plains Milk Snake). USA: COLORADO: BACA CO: AOR Co. Rd. VV, 1.6 mi E jct Co Rd. 27. 1 September 1996. UNC-MNH Photographs 20–21. Verified by Hobart M. Smith and David Chiszar. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **CHAD MONTGOMERY, JUSTIN HOBERT, ENOCH BERGMAN, BEN HILL, SCOTT BOBACK,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

MASTICOPHIS FLAGELLUM TESTACEUS (Western Coachwhip). USA: COLORADO: ARAPAHOE CO: Aurora, 21901 Hampden Avenue, Colorado Grange Museum, Plains Conservation Center, crawl space. 12 May 1992. T. Arneill, L. Czupryna, and F. Blanchard. UCM Herpetological Photographic Collection 130–131. Verified by Richard L. Holland. First county record; known range extension of 55 airline mi NW of nearest record to the SE, in NE El Paso County (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife, Denver. 131 pp.).

Submitted by **FRAN BLANCHARD, T. ARNEILL,** and **L. CZUPRYNA**, Plains Conservation Center, 21901 Hampden Avenue, Aurora, Colorado 80013, USA; **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

PSOMOPHIS GENIMACULATUS (Spirit Ground Snake). ARGENTINA: FORMOSA: DEPARTAMENTO BERMEJO: Reserva Natural Formosa (24°18'S, 61°45'W). 29 June 1995. M. L. Lions and J. Cespedez. Herpetological collection of Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 04938). Verified by G. Scrocchi. First province record and second record for Argentina.

Submitted by **MARIA LUISA LIONS** and **BLANCA BEATRIZ ALVAREZ**, Compared Anatomy Division, Biology Department, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, 3400 Corrientes, Argentina.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). CENTRAL AFRICAN REPUBLIC: Bangui: pk 5. 31 January 1996. Laurent Chirio. Museum national d'Histoire naturelle, Paris (MNHN 1996.6760). Verified by Van Wallach. First report for the country and for inland Africa. Previously only known from coastal areas of Africa (Nussbaum 1980, Herpetologica 36:215–221; Trape 1990, Bull. Soc. Herp. France 55:40–41).

Submitted by **LAURENT CHIRIO** and **IVAN INEICH**, Museum national d'Histoire naturelle, Laboratoire de Zoologie (Reptiles & Amphibiens), 25 rue Cuvier, F-75005 Paris, France. E-mail: ineich@cimrs1.mnhn.fr

RHINOCHEILUS LECONTEI TESSELLATUS (Texas Longnose Snake). USA: COLORADO: KIOWA CO: DOR, Rt. 287, 3.3 mi N jct Co. Rd. V. 5 September 1996. UNC-MNH 314. Verified by Hobart M. Smith and David Chiszar. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **BEN HILL, ENOCH BERGMAN, CHAD MONTGOMERY, JUSTIN HOBERT, SCOTT BOBACK**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga) USA: COLORADO: PROWERS CO: DOR, Rt 287 ca. 50 m N jct. Prowers/Baca County line. 21 August 1996. UNC-MNH 212. Verified by Hobart M. Smith and David Chiszar. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **JUSTIN HOBERT, SCOTT BOBACK, CHAD MONTGOMERY, ENOCH BERGMAN, BEN HILL**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences,

TROPIDOCLONION LINEATUM LINEATUM (Lined Snake) USA: COLORADO: CHEYENNE CO: DOR, Rt 287, 3.1 mi W jct Co Rd. 8. 5 September 1996. UNC-MNH 186. Verified by Hobart M. Smith and David Chiszar. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **ENOCH BERGMAN, BEN HILL, CHAD MONTGOMERY, JUSTIN HOBERT, SCOTT BOBACK**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

TYPHLOPS PORRECTUS (Slender Worm Snake). THAILAND: CHIANG MAI PROVINCE: Doi Pui (Pui Mtn., ca. 20 km NW of city of Chiang Mai in Doi Suthep Range), 18°50'N, 98°54'E, 1300 m. Thai National Reference Collection, Bangkok (TNRC 523–607). Verified by Van Wallach. Known from Pakistan, India, Bangladesh, Sri Lanka, and Myanmar (Hahn 1980, Das Tierreich 101:67; Khan 1988, Hamadryad 13:5); first record for Thailand. Extends known range eastward from Pyawbwe and Pegu (MCZ 3702), Myanmar by ca. 400 km.

Submitted by **MEREL J. COX**, 695/17 Pracharaj Road, Soi Pracharaj 19, Bangsue, Bangkok 10800, Thailand, and **JARUJIN NABHITABHATA**, Thailand Institute of Scientific and Technological Research, 196 Phahonyothin Road, Bangkhen, Bangkok 10900, Thailand.

Anuran Records from the Piedmont of South Carolina, USA

WILLIAM E. SNYDER
and
STEVEN G. PLATT
Department of Biological Sciences, Clemson University
Clemson, South Carolina 29634-1903, USA

Collecting in the piedmont of northwestern South Carolina has revealed several anuran distribution records based on comparisons with range maps of Martof et al. (1980), and localities listed in Chamberlain (1939) and Penny (1952). Voucher specimens were deposited in the Clemson University Vertebrate Collection (CUSC). Each specimen represents a county record. Identification was verified by Richard R. Montanucci unless otherwise stated.

Hyla cinerea (Green Treefrog). GREENWOOD CO: beaver swamp along Reedy Branch of Long Cane Creek at S. C. Rt. 112 bridge, ca. 5 km NW Bradley, Sumter National Forest. 21 August 1995. Steven G. Platt. CUSC 1266.

Hyla cinerea (Green Treefrog). ABBEVILLE CO: swamp along Mountain Creek ca. 0.25 km downstream from Parsons Mountain Lake Recreation Area, Sumter National Forest. 21 August 1995. Steven G. Platt. CUSC 1267.

Hyla cinerea (Green Treefrog). MCCORMICK CO: beaver swamp, Long Cane Creek Arm of Clark Hill Reservoir at jct. S. C. Rts. 28 and 8, ca. 13.3 km NW of McCormick. 2 September 1995. CUSC 1270.

Hyla cinerea (Green Treefrog). ANDERSON CO: Big Generostee Creek at S. C. Rt. 412, 1.5 km E jct. S. C. Rt. 187, ca. 6.5 km NW Starr. 12 July 1990. Amanda Billings. Verified by Tom Mann. CUSC 899.

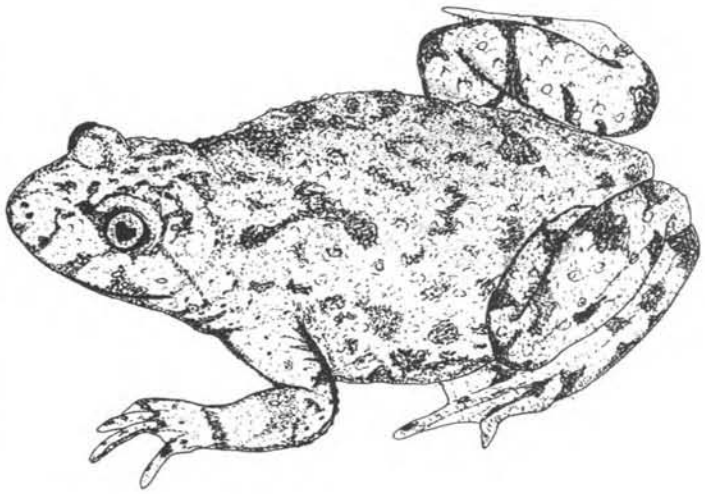
These records of *Hyla cinerea* represent a significant range expansion in the Savannah River drainage, from the coastal plain north into the piedmont. It is unclear whether previous workers overlooked *Hyla cinerea* in these counties or a recent range expansion has occurred in response to major habitat alterations.

Hyla squirella (Squirrel Treefrog). EDGEFIELD CO: ditches at jct. S. C. Rts. 230 and 23, ca. 10.5 km W of Edgefield, Sumter National Forest. 25 August 1995. Steven G. Platt. CUSC 1268.

Hyla gratiosa (Barking Treefrog). EDGEFIELD CO: Forest Service Road 639 at Lick Fork Lake Campground, Lick Fork Lake Recreation Area, ca. 3 km S jct. S. C. Rts. 23 and 230, Sumter National Forest. 25 August 1995. Steven G. Platt. CUSC 1273.

Hyla gratiosa (Barking Treefrog). GREENWOOD CO: Verdery, S. C. Rt. 47, ca. 0.9 km W of jct. S. C. Rt. 10. 26 August 1995. Steven G. Platt. CUSC 1269.

Bufo terrestris (Southern Toad). MCCORMICK CO: Clarks Hill, abandoned homesite, U. S. Rt. 28, ca. 3.3 km S jct. S. C. Rt. 88. April 1994. William E. Snyder and Steven G. Platt. CUSC 1137.



Acknowledgments.—Julian R. Harrison and Richard R. Montanucci reviewed an early draft of this manuscript. Stanlee Miller assisted with specimen preparation, and John Scavo, B. Anne Ditte, and Hong Liu assisted in fieldwork.

BOOK REVIEWS

Contributions to West Indian Herpetology: A Tribute to Albert Schwartz, edited by Robert Powell and Robert W. Henderson. 1996. Society for the Study of Amphibians and Reptiles: 457 pp. Hardcover. US $60 plus shipping. ISBN 0-916984-37-0.

BRIAN I. CROTHER
Department of Biology, Southeastern Louisiana University
Hammond, Louisiana 70402, USA
e-mail: bcrother@selu.edu

The basis of this volume comes from an SSAR symposium held in 1994 in honor of Albert Schwartz (because I knew him well, I will use Al), who had passed away two years prior. Arguably, anyone working on West Indian biology (not just herpetology, although his greatest contributions were there) knew Al's work, and it is unfortunate such a volume in his honor was not done while he was alive. There is one now (and another on the way) and I think Al would have approved.

I said "basis" above because the book is more than a typical symposium volume in that it contains, besides the symposium papers, a list of all Al's herpetological publications, a checklist of West Indian amphibians and reptiles, and color plates. The checklist includes 622 species (up from 585 species in Schwartz and Henderson, 1991) with each annotated account containing general distribution information, type locality, the complete citation of the original description, and the best source of pertinent literature. This latter feature unfortunately appears to be restricted to species accounts in the *Catalogue of American Amphibians and Reptiles*. Thus, for example, in the accounts of the two *Bothrops* species one is not referred to Campbell and Lamar's (1989) work on venomous reptiles of Latin America. This is, however, a trivial criticism. A more serious criticism of the checklist is that the authors (Powell, Henderson, Adler, and Dundee) implemented new taxonomies without formal argumentation. The checklist put *Peltaphryne* in synonymy with *Bufo* (contrary to Pregill 1981) and synonymized the anguid genera *Sauresia, Wetmorena*, and four species of *Diploglossus* with *Celestus*. In addition, the changes to anguid taxa were done without reference to Savage and Lips (1993) who used formal arguments to revise the same genera. Savage and Lips (1993) retained *Sauresia* and *Wetmorena*, but put the same *Diploglossus* species in *Celestus*.

There are 71 color plates of living specimens, 33 of which are lizards (including two amphisbaenids), 23 snakes, 12 frogs, 2 turtles and 1 crocodilian. Most of the plates are 3.5" x 2.25" with a few smaller, but they are largely of good quality. Arguably, the standout is the gaudy *Anolis bahorucoensis*, but the gaping mouth of *Cyclura nubila* and the upright pose of *Mastigodryas bruesi* are also classic.

The book is divided into seven parts: 1) a preface with a forward (Schoener) and introduction (Powell and Henderson); 2) an Albert Schwartz section with personal commentaries from William Duellman, Richard Thomas, and Robert Henderson; 3) a West Indian herpetology section composed of a brief history, the checklist, and the color plates; 4) a section on Evolution, Systematics and Biogeography (8 papers); 5) Ecology and Behavior (12 papers); 6) Conservation (7 papers); and 8) additional abstracts from papers presented at the symposium (9 abstracts). Except for the preface and the personal remembrances, all the papers are summarized in French and Spanish (a nice touch). The literature cited is at the end of each paper and the index is devoted to scientific names.

The first two parts of the book are essentially personal accounts, stories and commentaries on the West Indies and Albert Schwartz. Some of the stories are quite entertaining, my favorite being Bill Duellman's account of Al laying out his first salamanders for fixing in formalin. The only paper in the third part gives a history of West Indian herpetology. This is not an easy task, but the authors cover a lot of ground in a short space and the chapter ends up providing a fine introduction to the subject.

The next three parts (four–six) contain a somewhat eclectic collection of research papers tied together by the fact they all were conducted in the West Indies or on West Indian organisms. The fourth part (evolution for simplicity) has papers on *Eleutherodactylus* (2 papers), *Osteopilus*, and *Sphaerodactylus* phylogeny, *Trachemys* biogeography, speciation in Jamaica, dispersal (or the lack thereof) between South America and the Lesser Antilles, and the origin of West Indian herpetofauna.

The fifth part (ecology and behavior) has a number of taxon-specific studies, including *Eleutherodactylus* (3 papers), *Osteopilus* (2), anoles (2), *Ameiva, Alsophis*, and *Epicrates* as well as two more general papers. One is on a rain forest food web in Puerto Rico and the other concerns spatial niche partitioning in a Hispaniolan lizard community. The sixth part (conservation) is comprised of papers concerning the species richness of the Exuma Cays, declining amphibians of Puerto Rico, sea turtle populations in Haiti, and several species-specific papers on *Cyclura collei, Epicrates monensis, Corallus hortulanus*, and *Crocodilus acutus*. The seventh part, the abstracts, contribute little to the volume and easily could have been omitted.

In general the contributions are all well written and edited (in my readings I found few errors). Among the 31 papers in this volume, I found two of more importance (for quite different reasons) than the others. One of the papers is on the origin of the West Indian herpetofauna (Hedges) and the other is on the documentation of declining amphibians in Puerto Rico (Joglar and Burrowes). Perhaps the most provocative, and what it provokes will depend on the reader, passage in the volume comes from Lazell's paper on speciation in Jamaica:

> "Real evolution frequently involves paraphyly, polyphyly, and parallelophyly. The symplesiomorphy of reproductive continuity may amalgamate and obliterate clades regardless of their ages. Dogmatic philosophies that attempt to codify 'relationship' while ignoring evolutionary realities are not of practical value for comprehending the real world—the world of lizards."

The paper by Joglar and Burrowes is significant because it adds documentation to a global phenomenon that is still in need of rising above the label of factoid. Yes, there is a task force addressing the problem, but that alone is not enough. The 1994 *Herpetologica* Points of View papers on the subject of amphibian decline carried a high level of uncertainty in their pages with regard to the decline's causes and even its reality. There is clearly a major disturbance (not counting habitat destruction) to which amphibians appear to be sensitive. Stebbins and Cohen (1995) suggest that chemicals may be involved in altering amphibian hormone levels and/or immune responses which in turn may affect development. Another possibility is that external agents (e.g., chemicals, UV radiation) may be opening up the amphibians to viruses which were previously non-lethal (Jay M. Savage, pers. comm.). Savage based his idea on the apparent stepping stone fashion in which amphibian populations are disappearing in Costa Rica. Regardless of the mechanism, studies like that of Joglar and Burrowes are important for localizing declining populations, and these populations

should become the focus of detailed work to at least get at secondary causes, if not the primary cause. In their conclusion, they hypothesize that similar declines are probably occurring in the Greater Antillean islands. I wonder what the frog populations are currently like at Al's favorite collecting sites of days gone by?

The one manuscript that is arguably the most contentious of all the studies in this volume, is Hedges' deliberation on the origin of the West Indian herpetofauna. The paper is an expansion of the Hedges et al. 1992 work in which an albumin immunological distance-based molecular clock was employed to test between dispersal and vicariance hypotheses for the origin of the herpetofauna. The conclusion in the 1992 paper and in this volume is the same: dispersal accounts for all the current West Indian herpetofauna, with the possible exception of *Eleutherodactylus* and *Cricosaura*, and he hedges on both of those decisions. For space considerations, I refer readers to two papers (Crother and Guyer 1996; Page and Lydeard 1994) that examine in detail different aspects of the Hedges et al. (1992) work and as such they also apply to the Hedges paper in this volume. To encapsulate, the two papers reject (for explicit reasons) the assertion that dispersal is the primary explanation for the origin of the West Indian herpetofauna.

There are a number of items in the Hedges paper in this volume worth discussing, but I will touch on only a few here and those are mostly items that do not overlap with Page and Lydeard (1994) and Crother and Guyer (1996). The representation of vicariance and dispersal models is uneven. The discussion of the proto-Antilles existence as questionable is askew. The existence of the Great Arc (= proto-Antilles) is not contested in the geological literature and is in fact important in dinosaur (and other vertebrates) exchange between North and South America (e.g., Gayet et al. 1992). The argument that the Dominican amber fossils are lower Miocene is unsubstantiated (see Poinar and Cannatella 1987; but see Grimaldi 1995). Hedges makes taxonomic judgements based on the immunological distance data, including the rejection of *Peltaphryne* (Pregill 1981) and the iguanian lizard classification of Frost and Etheridge (1989). The rejection of the latter is based on his conclusion that *Leiocephalus* is actually more closely related to *Crotaphytus* than to the South American lineages of *Stenocercus, Tropidurus*, or *Liolaemus* as suggested by Etheridge (1966), Frost (1987), Frost and Etheridge (1989), and corroborated by Pregill (1992). These are examples of a disturbing implication by Hedges that molecular data are inherently superior to morphological data. Interestingly, three studies in this volume (Anderson [*Osteopilus*], Lynch [*Eleutherodactylus*], and Kaiser [*Eleutherodactylus*]) disagree with Hedges' ideas on phylogeny.

Although the Hedges paper is a weak link in an otherwise fine volume, it should engender much discussion, but hopefully won't be blindly cited as THE explanation for the origin of the West Indian herpetofauna.

The handsomely jacketed volume (there are pictures of hand colored lithographs of *Chamaeleolis chamaelionides* and *Tropidophis maculatus* from Ramon de la Sagra's "Historia Fisica, Politica y Natural de la Isla de Cuba," Paris, 1838–1861) is worth the $60 (US). I highly recommend it not only for the reference information (history, checklist, Schwartz publications, color plates) but also for the broad array of interesting and sometimes arguably contentious studies. All in all, the editors (and authors) have done a fine job. Al would have appreciated it.

Acknowledgment.—I am grateful to Mary White for her comments on the review.

e-mail: bpmm490@wadnr.gov

In many parts of the world, there is an urgent need to document the distribution and abundance of amphibians. Sadly, the need for these data is driven in large part by the suspicion that many amphibian species are currently in decline. Nowhere does the amphibian decline problem seem more apparent than in the western United States and Canada, where seventeen species of frogs and toads reportedly have experienced declines (Stebbins and Cohen 1995). Fortunately, many groups are supporting efforts to assess the status of amphibian populations in portions of this region. As these groups gear up for this challenge, however, they often lack the resources to train persons interested in participating in survey efforts. *Pacific States Frog and Toad Calls: Vanishing Voices*, produced jointly by the Library of Natural Sound and the U.S. Forest Service, will serve as an important resource.

This guide presents recordings of the frog and toad calls of the North American Pacific Coast between northern Baja California and Alaska. The stated goal of the guide is to assist listeners to learn to identify the calls of the frogs and toads of the region. The CD (or cassette) contains recordings of twenty-five of the twenty-eight anurans known to inhabit the region; calls of *Ascaphus truei* (which is thought to be mute), *Pseudacris triseriata* (which barely enters the northeastern corner of British Columbia) and *Rana pretiosa* (see subsequent comments) have been omitted from the guide. The 63 minutes of recordings are organized into four parts: a reference section, a comparison of similar-sounding species, a test section, and longer recordings of selected choruses.

The recordings in the reference section are arranged in alphabetical order by family. This organization of calls facilitates comparing the calls of closely related species, and following along in *A Field Guide to Western Reptiles and Amphibians* (Stebbins 1985). The section includes thirty-nine different recordings, with at least one recording for each of the twenty-five species covered. Eight species are covered with additional recordings, illustrating subspecies differences, group choruses vs. individual calls, different call types (e.g., advertisement, release, alarm), and, in one instance, above-water and below-water calls.

Prior to a species' recording, Davidson gives the common and scientific name of the species, provides a phonetic description of the call, and describes the type(s) of calls that are to follow. The twenty-seven page booklet that accompanies the CD provides additional information on the calls, technical data for each recording, descriptions of calls, and breeding periods. The quality of every recording is exceptional. Davidson obviously went to great lengths to obtain and select the best available recordings.

Part two of the guide presents comparisons of the calls of similar-sounding species for three groups: bufonids (*Bufo alvarius, B. woodhousii, B. punctatus, B. microscaphus, B. californicus*, and *B. cognatus*), hylids (*Hyla cadaverina* and *H. regilla*), and ranids (*Rana boylii* and *R. muscosa*). This section will be of interest primarily to those living in the areas where there is an overlap in the ranges of the treated species.

The test section is divided into northern and southern test regions. The northern region includes coastal species occurring north of San Francisco, California and inland species north of the Sierra Nevada. The southern test section includes species occurring south of San Francisco and in the Sierra Nevada Range. In each of the two test sections, listeners are allowed to test their call recognition skills by listening to the call before Davidson reads the species name.

The final section contains five additional recordings chosen for their beauty. These recordings play for nine minutes without interruption. Chosen more for their musical quality than their potential to teach call identification skills, each is a welcomed part of the CD.

It is virtually impossible to publish a guide that will not rapidly be outdated in some regards because of systematic advances and changes in taxonomy. This CD is no exception. The on-going debate concerning *Hyla regilla/Pseudacris regilla* rears its head here. Davidson, like other authors, appears trapped in the middle of the taxonomic tug-of-war as to the rightful place of *regilla—Hyla, Pseudacris*, or some yet to be named genus (Cocroft 1994; Hedges 1986). Nonetheless, the most recent evidence suggests that *Hyla* is the most appropriate genus for *regilla*. A more significant problem concerns the recent revision of the *Rana pretiosa* complex (Green et al. 1996, and in press). The guide was completed just prior to the revision, which splits *R. pretiosa* into two species, *R. pretiosa* and *R. luteiventris*, both of which occur in the area covered by the guide. As a result, the guide identifies a recording of *Rana luteiventris* as *Rana pretiosa*, and lacks a recording of *Rana pretiosa*. This should not pose a significant problem to survey efforts, as the two species have similar sounding calls. Future editions should address these problems.

The guide achieves its goal in every regard. It will provide naturalists and herpetologists with an outstanding reference on frog and toad calls of the Pacific Coast of the United States and Canada. In addition to assisting with survey efforts, these recordings will almost certainly lead to an increased appreciation and awareness of the natural beauty of the frogs and toads of the Pacific Coast region.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). E-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1997 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July (Theodore Pietsch, Chair).
1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
1997 ANNUAL MEETING
together with
AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS
and
THE HERPETOLOGISTS' LEAGUE
26 June – 2 July 1997
University of Washington, Seattle, USA

Keynote Address: "FROGS, UNPREDICTABILITY, FLEXIBILITY, AND THE FUTURE," by Martha Crump (Northern Arizona University).

Symposium: "NUCLEAR DNA AND THE EVOLUTIONARY GENETICS OF FISHES, AMPHIBIANS AND REPTILES." *Organizer*: Andrew M. Shedlock, University of Washington, FTR, Box 355100, Seattle, Washington 98195, USA; e-mail: shedlock@u.washington.edu.

Symposium: "ECOLOGICAL PROCESSES: INSIGHTS FROM FIELD EXPERIMENTS AND NATURAL HISTORY." This symposium celebrates the career and contributions of Margaret McBride Stewart in honor of her 70th birthday. *Organizer:* Kiisa C. Nishikawa, Department of Biological Sciences, Northern Arizona University, Flagstaff, Arizona 86011-5640, USA; e-mail: Kiisa.Nishikawa@nau.edu.

Symposium: "COMPARISONS AND CURRENT USES OF PHYLOGENETIC APPROACHES TO ICHTHYOLOGY AND HERPETOLOGY." *Organizer*: Mark Pyron, Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA; e-mail: Pyron@uiuc.edu.

Symposium: "CHEMICAL ECOLOGY OF PREDATOR/PREY RELATIONSHIPS AMONG FISHES, AMPHIBIANS, AND REPTILES." *Organizer*: Alicia Mathis, Department of Biology, Southwest Missouri State University, Springfield, Missouri 65804-0095, USA; e-mail: sam477f@vma.smsu.edu.

Symposium: "LIFE HISTORY AND ECOLOGY OF CHELONIANS." *Organizer*: R. Bruce Bury, National Biological Service, 3080 SE Clearwater Drive, Corvallis, Oregon 97333, USA; e-mail: buryb@mail.cor.epa.gov.

Symposium: "BIOSYSTEMATICS, BEHAVIORAL ECOLOGY, AND CONSERVATION OF IGUANAS." *Organizer:* William K. Hayes, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA; e-mail: whayes@ccmail.llu.edu.

Conservation Forum: Point-Counterpoint. "SUSTAINABLE USE OF AMPHIBIAN AND REPTILE RESOURCES." *Organizer:* C. Kenneth Dodd, Jr., SSAR Conservation Committee, 5222 NW 56th Court, Gainesville, Florida 32653, USA; e-mail: kdodd@nervm.nerc.ufl.edu.

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day in or near the University of Washington's Husky Union Building. Poster sessions will be held at the HUB.

Student Paper Awards: Seibert Prizes will be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize).

Multimedia Presentations: "HERPS OF THE WEST" and "AMPHIBIANS OF THE APPALACHIANS" by David Dennis and Eric Juterbock; "HERPETOLOGICAL NAMESAKES" by Kraig Adler and David Dennis.

Social Activities: General Reception at Seattle Aquarium, Auction, Salmon Barbecue, Graduate Student Reception, Banquet.

Live Exhibit: Live herps of the Pacific Northwest, sponsored by the Society for Northwestern Vertebrate Biology and the Pacific Northwest Amphibian and Reptile Consortium. As usual, a diverse array of animals will be available for viewing and photography.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Field Trips: Mount Saint Helens National Volcanic Monument and Snoqualmie Pass–Ellensburg.

Costs: Pre-registration US $120 regular, $60 student, $60 accompanying person. After March 15, costs are $145 regular, $75 student, and $75 accompanying person.

Further Details: Contact T. W. Pietsch, School of Fisheries, University of Washington, Box 355100, Seattle, Washington 98195-5100, USA. Tel. (206) 543-8923; e-mail: twp@fish.washington.edu. Meeting Announcement and Call for Papers were mailed to all U.S., Mexican, and Canadian members of SSAR in late November 1996. Other persons wishing to receive this information may do so by contacting Ted Pietsch at the address above. A World Wide Web page devoted to meeting information may be found at: http://artedi.fish.washington.edu/asih/asih97.html.

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as President for 1998) ..... *Darrel Frost.*

Secretary ..... *Ellen Censky* (unopposed).

Treasurer ..... *Robert Aldridge* (unopposed).

Directors ..... *Charles Painter, R. Wayne Van Devender.*

HR Staff Changes

Because of what seems like a never-ending increase in the number of manuscript submissions to *HR*, it has become necessary to restructure our editorial staff. We have added six new Associate Editors to handle the review process for all general article, point of view, and techniques manuscripts. These new positions will be filled by Daniel Beck (Central Washington University), Brian Bowen (University of Florida), Lee Fitzgerald (Texas A&M University), Daryl Karns (Hanover College), Jeff Lovich (U.S. Geological Survey), and Deanna Olson (U.S. Forest Service). Manuscript submissions should continue to be sent to the Editor (Hansen), who will acknowledge receipt and assign the ms. to an Associate Editor. The Associate Editor will handle all reviews and communicate the results to the author. These changes should shorten the review process for most manuscripts.

Lee Fitzgerald's move to Associate Editor creates a vacancy for Natural History Notes, where Lee handled hundreds of submissions over a three-year period. That role will now be assumed by Kathryn Vaughan (Texas A&M), who will handle the NHN submissions for lizards, amphisbaenians, crocodilians, and Sphenodontia. Future contributors to Natural History Notes should consult that section elsewhere in this issue for manuscript submission details.

SSAR Student Travel Awards Fund-Raiser: Call For 1997 Donations

Continuing a successful tradition, the SSAR Student Travel Awards Committee proudly announces the Fourth Annual Frameable Art Silent Auction to be held at the 1997 SSAR meeting in Seattle. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: *John Lee, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA; tel. 803-725-5873; e-mail: LEE@SREL.EDU.*

SSAR Student Travel Awards Call for Applications

Ten awards of $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author (or co-author, see below) of a paper or poster to be presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that states: he/she currently is an undergraduate or graduate student and that he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Student Travel Awards Committee are excluded from applying for a travel award. APPLICATIONS MUST BE POSTMARKED BY 15 MAY 1997.

About Our Cover: *Bothrops insularis*

About 30 species of pitvipers of the genus *Bothrops* currently are known, nearly two-thirds of them occurring in Brazil (including several endemics). Recent studies indicate that the traditional taxonomy and the phylogenetic affinities in the genus *Bothrops* still are poorly resolved. The threatened golden pitviper (or jararaca ilhoa), *Bothrops insularis*, probably a sister species of the mainland, widespread *Bothrops jararaca*, is endemic to the small island of Queimada Grande (43 ha), located about 30 km offshore from the city of Itanhaém, state of São Paulo, southeastern Brazil. It occurs in extremely high densities—up to 60 snakes may be found in a single day's field work—on trees, shrubs, and on the ground of the low Atlantic forest that covers most of the island. Primary prey are migratory passerine birds, although centipedes, anurans, lizards, amphisbaenians, and snakes occasionally are eaten. The venom is highly toxic, about five times more toxic to birds than that of *B. jararaca*. One of the few snakes in which intersexuality is known (probably the result of intensive inbreeding), *B. insularis* has a relatively small litter size, and the reproductive population is apparently decreasing. Sexual abnormalities in *B. insularis* were described and discussed by Hoge et al. (1959. Mem. Inst. Butantan 27:17–88) and more recently Duarte et al. (1995. Stud. Neotr. Fauna Environ. 30:1–13) provided a thorough review of its natural history.

A research team from the Instituto Butantan, the Universidade de São Paulo, and the Universidade Estadual de Campinas currently is carrying on a long-term study (begun in 1995, with monthly visits to the island) of the natural history and population biology of the golden pitviper. The principal aim of the study is to gather good field data to subsidize a future conservation program for this highly interesting and threatened pitviper.

Our cover photo was taken by **Marcio Martins**, a postdoctoral fellow at the Departamento de Zoologia of the Universidade Estadual Paulista at Rio Claro, and recently appointed a Professor at the Departamento de Ecologia Geral of the Universidade de São Paulo, at São Paulo, Brazil. He finished his Ph.D. in Ecology at the Universidade Estadual de Campinas in 1994 with a long term study focusing on the organization of a forest snake assemblage in Central Amazonia. Currently, Martins is writing a book and several articles on Amazonian snakes and other herps, participating in a herpetofaunal survey at Rondônia, southwestern Amazonian Brazil. He also is beginning a long-term study exploring how natural history traits (feeding habits, habitat use, reproduction, defense) evolved in pitvipers of the genus *Bothrops* (sensu lato), including participation in the study of *Bothrops insularis* described above. The photograph was taken in the morning inside a low forest on Queimada Grande Island in October 1996 with a Nikon F-301 camera, Nikkor 55mm f 1:2.8 micro lens at f11, shutter speed 1/125 s, and a Nikon SB-25 flash (in manual mode) with a SW-6 wide-flash adapter, using Fujichrome Provia ISO 100 film. The subject is an intersex, 730 mm total length, and was as little disturbed as possible before being photographed.

Separation and imaging of Martins' photograph is the work of **Jim Bridges** of Herpeto Inc., Hollywood, Florida, USA.

Award recipients will be notified by 1 June 1997 and award checks will be disbursed at the meeting. Requests for information on making donations and applications for awards should be sent to: *John Lee, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA; tel. 803-725-5873; e-mail: LEE@SREL.EDU.*

Items Needed for SSAR Auction in Seattle

Once again, Joe Collins will be conducting the SSAR auction during the annual meeting at the University of Washington in June 1997. All proceeds from the auction go to the SSAR treasury, and help to continue the production of the diverse publications and services for which SSAR is known. Items of value as well as those that lend themselves to humor are always welcome. Joe is skilled at removing large quantities of cash from auction participants through the judicious use of beer and plastic. Auction items may be brought directly to the meeting or sent in advance (clearly marked "Herp Auction") to: *Ted Pietsch, School of Fisheries, 1140 Boat Street, University of Washington, Box 355100, Seattle, Washington 98195-5100, USA.*

NEWSNOTES

Southwestern Research Station Positions And Grants For 1997

VOLUNTEERS—Approximately 30 volunteer positions are open in 1997 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for Spring positions (March–May) should submit applications by February 15, Summer volunteers (June–August) by April 1, and Fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 1997. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396.*

Summer Course on Larval Amphibian Biology at Highlands Biological Station

A course on Larval Amphibian Biology will be taught at Highlands Biological Station June 2–13, 1997. Instructors are Richard Wassersug, Ray Semlitsch, Richard Bruce, and Travis Ryan. This is a lecture, laboratory, and field course addressing a variety of topics on the biology of amphibian larvae. Three semester hours credit at the advanced undergraduate/graduate level are available through either Western Carolina University or the University of North Carolina at Chapel Hill. For further information contact: *Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA. Tel. (704) 526-2602, FAX (704) 526-2797, e-mail: bruce@wcu.edu.*

Duellman Retires from The University of Kansas

William E. Duellman, long-time Curator of Herpetology at The University of Kansas Natural History Museum and Professor of Systematics and Ecology, retired on 13 December 1996. He served at KU for 37 years, producing numerous graduate students who have gone on to careers in systematic herpetology. Duellman, the world's preeminent authority on frogs and co-author (with Linda Trueb) of *Biology of Amphibians*, will continue to work on books, research papers, and other projects in his retirement. The SSAR recognized Duellman's important contributions to herpetology by hosting a symposium in his honor at the 1996 annual meeting.

New Journal

Amphibian & Reptile Conservation made its debut in the Fall of 1996. This new peer-reviewed journal is devoted to the worldwide preservation and management of amphibian and reptilian diversity. The journal will publish articles, notes, commentaries, and book reviews, and is intended for a wide audience. For subscription information or other details, contact: *Amphibian & Reptile Conservation, 2255 North University Parkway No. 15, Provo, Utah 84604-7506, USA.*

Data Requested for Nigerian Snakes

Luca Luiselli is conducting ecological studies of snakes from rainforests and mangroves of Port Harcourt (Rivers State) and Calabar (southeastern Nigeria), and would appreciate any field data collected by other workers on free-ranging snakes from those areas. The following data are especially useful: sex, snout-vent length, tail length, body mass, and any prey or reproductive data. All contributors will be acknowledged in resulting publications, and the entire series of papers on Nigerian snakes will automatically be sent. Contact: *Dr. Luca Luiselli, Dept. Animal and Human Biology, via Olona 7, 1-00198 Rome, Italy. Fax: **39-6-8411964.*

Captive Research Iguanas & Monitors Available

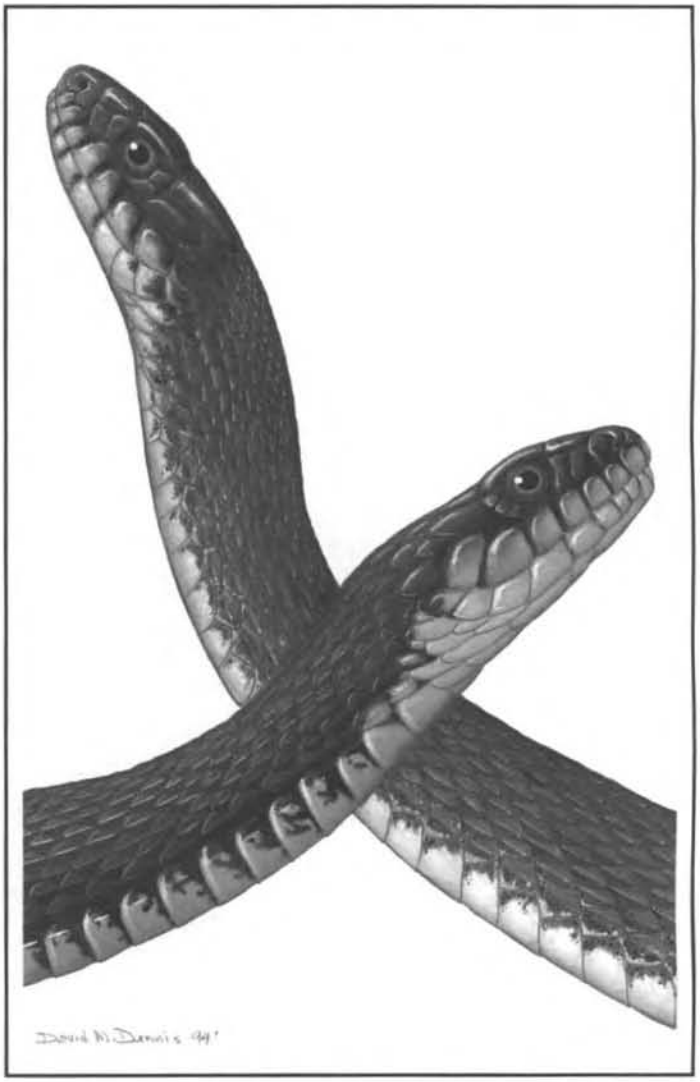
6.0 *Iguana iguana* (green iguana) and 0.0.8 *Varanus exanthematicus* (savanna monitor) are currently available for exhibition and non-terminal research from the Department of Zoological Research, National Zoological Park. Iguanas are 7 years old and monitors are approximately 4 years old. Animals offered are gratis to approved institutions and individuals, receive preshipment health screening, and are accompanied by individual histories. Shipping costs must be borne by receiving institutions. For further information, please contact: *Miles Roberts, Department of Zoological Research, National Zoological Park, Washington, D.C. 20008, USA; Tel: (202) 673-4749; FAX: (202) 673-4686; e-mail: nzpem030@sivm.si.edu.*

MEETINGS

Meetings Calendar

19 April 1997—All Florida Herpetology Conference, University of Florida, Gainesville, Florida, USA. Co-sponsored by the Florida Museum of Natural History and Gainesville Herpetological Society. Contact: David L. Auth, Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA. Tel. (352) 392-1721.

26 June–2 July 1997—40th Annual Meeting, Society for the Study of Amphibians and Reptiles; 45th Annual Meeting of The Herpetologists' League; 77th Annual Meeting, American Society of Ichthyologists and Herpetologists. Hosted by the University of Washington, Seattle, Washington, USA. *Refer to meeting announcement on page 1 of this issue for details.*



2–10 August 1997—Third World Congress of Herpetology, Prague, Czech Republic. Contact: Zbynek Roçek, Congress Director, Department of Paleontology, Geological Institute, Academy of Sciences, Rozvojová 135, 165 00 Praha 6 – Suchdol, Czech Republic. Tel. (++42-2) 24311421; Fax (++42-2) 24311578; e-mail: rocek@gli.cas.cz. *Refer to meeting announcement in* Herpetological Review *27(1):4–5, March 1996 for details.*

18–19 October 1997—First International Symposium on Snakebite. Zhanjiang, People's Republic of China. *Refer to meeting announcement on next page for details.*

1–3 June 1998—Biodiversity and Conservation of Amphibians and Reptiles of Tropical Forests: An International Symposium. Hanoi, Vietnam. *Refer to meeting announcement on next page for details.*

June 1998—Highlands Conference on Plethodontid Salamanders. Contact: Plethodontid Conference, Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA, or send an e-mail message to Judy Hill (HBS Admin. Asst.) at: JHILL@wpoff.wcu.edu. A more detailed announcement will appear in the June 1997 issue of *HR.*

1–5 September 1998—Third International Asian Herpetological Meeting, Almaty, Kazakhstan. *Refer to meeting announcement on next page for details.*

ENDANGERED WATER SNAKES: FULL-COLOR PRINT FOR FRAMING

The Society is pleased to offer a signed-and-numbered full-color print of two watersnakes (*Nerodia erythrogaster neglecta* and *N. sipedon insularum*) described by Roger Conant. The original watercolor, by the well-known natural history artist David M. Dennis, was originally published as the frontispiece in Murphy, Adler, and Collins (editors), "Captive Management and Conservation of Amphibians and Reptiles" (SSAR, 1994). These prints measure 9 1/2 x 12 inches (24 x 30 cm) and are personally signed by both Dr. Conant and Mr. Dennis. The edition is limited to only 450 copies. Proceeds from the sale of this print will go to conservation of these snakes.

Copies may be obtained for US$25 each plus $3 shipping from the SSAR Publications Secretary, Dr. Robert D. Aldridge, Department of Biology, Saint Louis University, 3507 Laclede Ave., Saint Louis, Missouri 63103, USA (*telephone*: 314-977-3916 or 977-1710; *e-mail*: ssar@sluvca.slu.edu; *fax*: 314-977-3658). Please make checks payable to "SSAR." Orders may be charged to MasterCard or VISA (provide account number and expiration date). A complete list of SSAR publications and membership information can be obtained on request from Dr. Aldridge.

Third International Asian Herpetological Meeting

The Third International Asian Herpetological Meeting will be held in Almaty, Kazakhstan from 1–5 September 1998. Preliminary plans call for the meeting to be organized around the following symposia: Paleoherpetology, Zoogeography of the Asian Herpetofauna, Conservation, Captive Breeding, Morpho-Functional Organization of Amphibian and Reptilian Integument, Molecular Taxonomy, as well as various symposia devoted to different herp groups (Salamandridae, Bufonidae, Agamidae, Varanidae, and Viperidae). The official language of the meeting will be English. To receive the First Announcement and Preliminary Registration Form, please contact one of the meeting organizers:

Dr. Tatjana Dujsebayeva, Department of Biology, Kazakh State University, Al-Farabi Prospect, 71, Almaty, 480078, Kazakhstan; Tel. (3272) 472677, Fax (3272) 472609, e-mail: zool@plague.almaty.kz.

Dr. Natalia Ananjeva, Department of Herpetology, Zoological Institute, Universitatskaja nab., 1, Saint-Petersburg, 199034, Russia; Tel. (812) 2180711, Fax (812) 2182941, e-mail: anb@zisp.spb.su.

Dr. Theodore Papenfuss, Asiatic Herpetological Research, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA; Tel. (510) 642-3567, Fax (510) 643-8238, e-mail: asiaherp@uclink2.berkeley.edu.

Biodiversity and Conservation of Amphibians and Reptiles of Tropical Forests

An international symposium—Biodiversity and Conservation of Amphibians and Reptiles of Tropical Forests—tentatively has been scheduled for 1–3 June 1998 at the Institute of Ecology and Biological Resources in Hanoi, Vietnam. All plenary lectures and contributed papers will be delivered in English. Posters may be in English, Vietnamese, Russian, German, or French. Plenary lectures are planned to address biodiversity and conservation of the herpetofauna of tropical forests of Vietnam, China, Laos, Indonesia, Philippines, Australasia, South and Central America, and Africa. For further details, contact: *Natalia Ananjeva (St. Petersburg, Russia), e-mail: nbanorus@glas.apc.org.*

1st International Symposium on Snakebite

To promote the study of emergency treatment of snakebite and to enhance international academic exchanges and cooperation, the 1st International Symposium on Snakebite will be held 18–19 October 1997 in the south coastal city of Zhanjiang, People's Republic of China. The symposium is jointly sponsored by the Asiatic Society of Preventing and Treating Snakebite and Zhanjiang Institute of Clinical Medicine. The deadline for submission of papers is 31 May 1997. To receive further information, contact: *Organizing Committee of the First International Symposium on Snakebite, No. 2 Cunjin Road, Zhanjiang City, Guangdong Province 524037, People's Republic of China. Tel./Fax 0086-759-3316724.*

"AMPHIBIANS OF HONDURAS" Color Slides Needed

Work on the book "The Amphibians of Honduras" by James R. McCranie and Larry David Wilson is in progress and will be published by the SSAR (probably in 1998). Any profits from the sale of the book will go to the Society. It is hoped that color slides of all species of amphibians known from the country (about 105 species) can be included in the book. Currently there are 15 species of non-endemics for which slides are needed.

If you have slides of any of the species listed below, please contact either of the authors (JRM: 10770 SW 164th Street, Miami, Florida 33157, USA; telephone 305-251-4270; fax 305-234-2320. LDW: Department of Biology, Miami-Dade Community College, Kendall Campus, Miami, Florida 33176, USA; telephone 305-237-2579; fax 305-237-0891). After information on slide availability is assembled, slides will be requested in late 1997. Unfortunately, no funds are available for the purchase of slides, but loans of needed slides (for one-time use) will be much appreciated and fully acknowledged in the book.

Species needed—*Gymnopis syntrema, Bolitoglossa occidentalis, B. striatula, Bufo haematiticus, Agalychnis calcarifer, A. moreletii, Hyla ebraccata, Plectrohyla glandulosa, Smilisca phaeota, Triprion petasatus, Eleutherodactylus biporcatus, E. mimus, E. rhodopis, E. rostralis,* and *Hypopachus barberi.*

A New Source of Both Ultra-Violet Light & Heat

This lamp screws into ordinary incandescent sockets (no ballast or fixture necessary), and puts out a beam of light that contains ultra-violet radiation. It has been tested for approximately 6-1/2 years at the

North Carolina Zoological Park.

For a no obligation copy of their report, please call:

Westron Corporation
at **1-800-221-4289**
3590C Oceanside Road
Oceanside, New York 11572

LEGISLATION & CONSERVATION

Call for information on the status of amphibians and reptiles. This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. Please direct all communications to the Section Editor.

USA: U.S. Fish and Wildlife Service: As of 12 April 1996, Australian populations of the saltwater crocodile (*Crocodylus porosus*) have been reclassified by the USFWS from endangered to threatened. Protective management strategies by the Australian government are in large part responsible for the saltwater crocodile's recovery and subsequent reclassification. The saltwater crocodile remains listed as endangered throughout the remainder of its range, except for Papua New Guinea, where the population never has been listed.

USA: U.S. Fish and Wildlife Service: As of 20 May 1996, the USFWS listed the California red-legged frog (*Rana aurora*) as Endangered under the U.S. Endangered Species Act. The State of California had previously listed the species as Special Concern under the state endangered species act. The largest remaining populations of red-legged frogs are found in three of California's coastal counties: Monterey, Santa Barbara, and San Luis Obispo. This region is also under some of the greatest development pressure. The red-legged frog was the first new listing of a species under the ESA since President Clinton signed the FY '96 budget bill that lifted the moratorium imposed by Congress on the listing of threatened or endangered species.

USA: Ohio: The State of Ohio has been strongly encouraged to implement an immediate statement of non-occurrence regarding the status of the wood turtle (*Clemmys insculpta*) in Ohio. Apparently, numerous specimens obtained by commercial collectors have been claimed as Ohio animals. The wood turtle is protected in most other states throughout its range. There are no verifiable records that any wild populations of wood turtles exist in Ohio or that any have in recent times. Statewide surveys conducted by Roger Conant in the 1920s and 30s failed to find a single wood turtle in Ohio. There are three isolated records of individual wood turtles being found in recent times (1948, 1952, and 1973) that are believed to represent captive and subsequently released or escaped individuals. Therefore, herpetologists and conservationists should be suspicious of any "Ohio" wood turtles offered for sale. For more information contact: *Daniel L. Rice, Chief Zoologist, Ohio Department of Natural Resources, Division of Natural Areas and Preserves, 1889 Fountain Square, Columbus, Ohio 43224, USA.*

USA: U.S. Fish and Wildlife Service: The United States has received proposals that proposed amendments to the appendices of CITES for the following species. These amendments, if submitted to CITES, would be considered at the tenth regular meeting of the Parties (COP10), June 9–20, 1997, Harare, Zimbabwe (Federal Register, Vol. 61, No. 168, 28 August 1996, pp. 44324–44342). 1) North American softshell turtles (*Apalone mutica, A. spinifera, A. ferox*) to Appendix II. All species are suggested as vulnerable to damming of rivers and loss of preferred habitat. All species are taken for human consumption and some animals enter the pet trade; 2) Map turtles (12 species of *Graptemys*) to Appendix II. Biologists who have studied seven of the species believe that populations have declined. At least four species are very popular in the pet trade. The USFWS believes that the combination of population vulnerability and international trade may qualify at least some of the species for inclusion under Appendix II; 3) Alligator snapping turtle (*Macroclemys temminckii*) to Appendix II. It is evident that the species has declined severely throughout much of its range. The primary causes of population decline appear to be degradation and damming of river systems and widespread commercial harvest for meat; 4) Gila monster and beaded lizard (*Heloderma* spp.) from Appendix II to Appendix I. Populations of both species are believed to be declining due to habitat degradation and local depletion by collectors for the pet trade. However, reliable data on wild populations are lacking; 5) Rattlesnakes (*Crotalus horridus, C. adamanteus*, and *C. atrox*) to Appendix II. Populations of *C. adamanteus* are declining due to loss of 90 percent of the original longleaf pine forest in the southeastern U.S. Populations of *C. horridus* have declined greatly over much of their original range and in many states only relict populations remain. The USFWS suggests that *C. atrox* should be proposed for listing due to its similarity of appearance to *C. adamanteus*; 6) Sail-fin lizards (*Hydrosaurus* spp., *Hypsilurus* spp., and *Physignathus lesuerii*) to Appendix II. These lizards are found in the southwestern Pacific region, including Australia, Philippines, eastern Indonesia, and New Guinea. Causes of decline vary for the different species but include loss of riparian forests (*Hydrosaurus* spp.), and general logging and habitat loss, as well as collection for the pet trade.

An update, issued by USFWS on 10 January 1997, indicates that the U.S. will propose action (as detailed above) for the following: all 12 species of *Graptemys, Malaclemys temminckii*, and *Crotalus horridus*.

European Union: As of 12 December 1996, the EU has adopted one of the most sophisticated and comprehensive wildlife trade laws in the world, entitled, "Council Regulation on the Protection of Species of Wild Fauna and Flora by Regulating Trade Therein." The EU is one of the largest legal wildlife markets for CITES-listed plants and animals in the world. Specifically, the new law requires member states to abide by all CITES regulations, establishes EU level bodies to provide enforcement, and imposes mandatory sanctions on member states who break the law. It also allows for control and monitoring of species not covered by CITES and provides stricter importation criteria than currently exists regarding an additional 25,000 species.

Sweden: A very unfortunate incident regarding 1000 Horsfields tortoises (*Testudo horsfieldi*) apparently took place in late October 1996. A shipment of 1000 tortoises was denied entry into Sweden because it lacked appropriate importation permits. Horsfields tortoises are not permitted to be imported into the European Union under existing wildlife trade laws. The Swedish authorities refused all offers by animal support groups to return the tortoises to their port of origin or other suggestions and apparently killed all the tortoises. This unfortunate incident brings up an issue that needs a policy solution. Although repatriation to native habitats is most likely not a viable alternative in these situations, it seems that captive breeding programs of rare species should be able to utilize these animals. Perhaps the issue deserves a response from the herpetological and conservation communities.

USA: U.S. Fish and Wildlife Service: The USFWS is proposing Endangered Species Act protection to conserve the remaining populations of the bog turtle (*Clemmys muhlenbergii*), which has seriously declined in the northeastern United States. The northern portion of the bog turtle's range, from New York and Massachusetts south to Maryland, would be designated Threatened. The southern population of the bog turtle, ranging from southern Virginia to northern Georgia, would be protected with a Threatened designation because its physical appearance is similar to the northern population.

The northern segment of the range has declined by 50 percent, mostly within the past 20 years. Illegal collection, primarily for the national and international pet trade, as well as loss and modification of the bog turtle's wetland habitat, have resulted in a reduction of the species' range and a decline in the size of remaining populations. Currently, bog turtles are known to remain at fewer than 200 sites in their northern range. Based on site habitat quality, only 35 of the 165 sites assessed may be capable of supporting a healthy bog turtle population in the future unless measures are taken to maintain or enhance bog turtle habitat.

For additional information or to provide comments, contact: *Carole Copeyon, Pennsylvania Field Office U.S. Fish and Wildlife Service, 315 South Allen Street, Suite 322, State College, Pennsylvania 16801, USA; tel. (814) 234-4090.*

USA: U.S. Fish and Wildlife Service: A diverse partnership of State, Federal, and private interests have joined together to help save the copperbelly water snake (*Nerodia erythrogaster neglecta*), an inhabitant of wetlands and bottomlands, and to protect its dwindling habitat. Landmark conservation agreements signed by three states, the Department of the Interior, and representatives of the coal mining and agriculture industries will keep the snake off the endangered species list in the southern part of its range in western Kentucky, southern Illinois, and southern Indiana.

USFWS has decided to list as threatened isolated remnant populations in the snakes's northern range, in northeastern Indiana, northwestern Ohio, and southern Michigan. Conversion of the snake's habitat in the north to roadways, building sites and agriculture continues to threaten these populations. It is estimated that these populations would vanish in the next 10–20 years without protection.

This snake historically ranged throughout much of the states of Michigan, Indiana, Illinois, Ohio, and Kentucky. However, loss of its habitat has reduced its range to pockets of remaining wetlands and bottomlands, which overlie coal fields in southern Indiana, southern Illinois, and western Kentucky. Today the largest number of copperbelly water snakes occurs in western Kentucky in 18 isolated populations. Only two of these are considered secure, with the others threatened by conversion of habitat to mining and cropland. In Indiana there are 13 populations, and five in Illinois.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: herpbooks@sisna.com. Comments and suggestions are also welcome.

The current contents of several herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are being listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Chelonian Research Foundation Publications

The Chelonian Research Foundation recently announced a new publication series, *Chelonian Research Monographs*. The first monograph was published earlier this year and reviews the current nomenclatural and population status of the Galápagos tortoises.

PRITCHARD, P. C. H. 1996. The Galápagos Tortoises: Nomenclatural and Survival Status. Chelonian Res. Monogr. (1):1–85.

The largest, and most recent issue of *Chelonian Conservation and Biology* is the journal's first Special Focus Issue. Appropriately this issue is devoted to the largest and most specialized turtle species in the world—the leatherback, *Dermochelys coriacea*. Articles are divided into four categories: nesting populations and conservation; biology and morphology; systematics and evolution; and translations.

BOULON, R. H., JR, P. H. DUTTON, AND D. L. MCDONALD. 1996. Leatherback turtles (*Dermochelys coriacea*) on St. Croix, U.S. Virgin Islands: Fifteen years of conservation. Chelonian Conser. Biol. 2(2):141–147.

Exploiting Exploitation of Monitors

Shine and colleagues examined 166 water monitors *(Varanus salvator*), collected for their skins, to gain insight into several aspects of their biology. Diet, fat storage, size at maturity, and clutch size were among the data collected. The authors also discuss the harvesting of water monitors in Sumatra.

Shine, R., P. S. Harlow, and J. S. Keogh. 1996. Commercial harvesting of giant lizards: The biology of water monitors *Varanus salvator* in southern Sumatra. Biol. Conserv. 77:125–134.

Amphibian Declines

Fisher and Shaffer combined broad-scale field sampling with historical analysis of museum records to quantify amphibian declines in California's Great Central Valley. They provide new evidence implicating introduced predators as a primary threat. In addition, their historical approach provides a strategy for identifying declining amphibian communities that compliments more detailed, long-term monitoring programs and provides an assessment of the pattern of change that is a necessary prerequisite for the development of field experiments that test hypothesized mechanisms of change.

Fisher, R. N., and H. B. Shaffer. 1996. The decline of amphibians in California's Great Central Valley. Conserv. Biol. 10(5):1387–1397.

Blaustein et al. assessed DNA repair and resistance to solar radiation in eggs of the red-legged frog (*Rana aurora*), a species whose populations appear to be in decline. They found photolyase levels in *R. aurora* to be relatively high when compared with other amphibians and hatching success to be unaffected by UV-B radiation. The suggest that UV-B radiation is an unlikely cause for declining populations of red-legged frogs.

Blaustein, A. R., et al. 1996. DNA repair activity and resistance to solar UV-B radiation in eggs of the red-legged frog. Conserv. Biol. 10(5):1398–1402.

Another New Salamander for California

Despite its status as the most populous state in the U.S., California continues to yield new species of amphibians. Wake describes a recently-discovered species of *Batrachoseps* (*B. gabrieli*) from two small areas of the San Gabriel Mountains of southern California. Although a member of the attenuate clade of *Batrachoseps, B. gabrieli* is strikingly distinct relative to other species based upon genetic comparisons, with lineage separation estimated at 8 to 13 million years. This paper is the first of several in which Wake and colleagues will report on the systematics of *Batrachoseps*.

Batrachoseps gabrieli, a distinctive new plethodontid from southern California. Photograph by Mario Garcia Paris, courtesy of David B. Wake.

Wake, D. B. 1996. A new species of *Batrachoseps* (Amphibia: Plethodontidae) from the San Gabriel Mountains, Southern California. Contr. Sci. Nat. Hist. Mus. Los Angeles Co. 463:1–12.

Rana pretiosa Species Complex

Using allozymes and morphology, Green et al. examined several populations of the spotted frog (*Rana pretiosa*). This species was shown to exhibit isolation-by-distance, genetic subdivision, and speciation in association with its extensive northward range shift in postglacial times. The authors discuss the relationship between two morphologically cryptic species that make up the *Rana pretiosa* complex.

Green, D. M., et al. 1996. Postglacial range fluctuation, genetic subdivision and speciation in the western North American spotted frog complex, *Rana pretiosa*. Evolution 50(1):374–390.

Feeding Kinematics in *Salamandra salamandra*

Two recent studies by Reilly examine the feeding kinematics of *Salamandra salamandra*. The first paper discusses the lack of ontogenetic change in feeding kinematics in salamander larvae. The second study examines the evolution of terrestrial prey capture as it relates to aquatic feeding behavior and prey transport.

REILLY, S. M. 1995. The ontogeny of aquatic feeding behavior in *Salamandra salamandra*: Stereotypy and isometry in feeding kinematics. J. Exp. Biol. 198:701–708.

REILLY, S. M. 1996. The metamorphosis of feeding kinematics in *Salamandra salamandra* and the evolution of terrestrial feeding behavior. J. Exp. Biol. 199:1219–1227.

Evolution of Sexual Dimorphism in Southeast Asian *Rana*

There are a number of species of southeast Asian *Rana* that are characterized by an unusual suite of sexually dimorphic features and derived reproductive modes. These frogs lack the usual secondary sexual characteristics of ranid frogs. Phylogenetic analysis using morphological and molecular data indicate that a drop in androgen level and/or a shift in androgen sensitivity may have been involved in the evolution of male parental care and the loss of the common suite of secondary sexual characteristics. This study is an example of how emergent properties from phylogentic analysis can be used to formulate and test hypotheses of process and pattern of evolutionary change.

EMERSON, S. B. 1996. Phylogenies and physiological processes—the evolution of sexual dimorphism in southeast Asian frogs. Syst. Biol. 45(3):278–289.

Systematics of Australian Chelidae

Georges and Adams examined allozymes of 222 specimens from 55 populations of chelid turtles in Australia and Papua New Guinea. They determined that if the phylogentic species concept is adopted, there is support for recognition of 16 species of short-necked turtles in Australia. Currently only 10 are described.

GEORGES, A., AND M. ADAMS. 1996. Electrophoretic delineation of species boundaries within the short-necked freshwater turtles of Australia (Testudines: Chelidae). Zool. J. Linn. Soc. 118:241–260.

Snake Mitochondrial DNA Sequences

In sequencing two major tRNA gene clusters in snake mtDNA, Kumazawa et al. found a sequence of approximately 1.3 kb inserted between the genes for $tRNA^{Ile}$ and $tRNA^{Gln}$. The insert contains a control-region-like sequence and was found in snakes from several different families. In three snakes examined, they found a similar control-region-like sequence in the region surrounded by genes for cytochrome *b* and 12S rRNA. The authors suggest the duplicate state of the control-region-like sequences has long persisted in snake mtDNA.

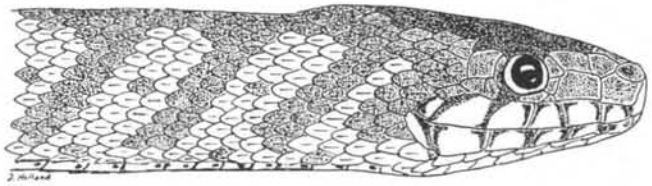
KUMAZAWA, Y., ET AL. 1996. Gene rearrangements in snake mitochondrial genomes: highly concerted evolution of control-region-like sequences duplicated and inserted into a tRNA gene center. Mol. Biol. Evol. 13(9):1242–1254.

Revision of the Genus *Lacerta*

Mayer and Bischoff examined the morphology and karyotypes of several species of *Lacerta*. Based on their data, the authors recommend that the currently recognized subgenera *Zootoca, Omanosaura, Timon,* and *Teira* be elevated to full genera.

MAYER, W., AND W. BISCHOFF. 1996. Beiträge zur taxonomischen Revision der Gattung *Lacerta* (Reptilia: Lacertidae). Teil 1: *Zootoca, Omanosaura, Timon* und *Teira* als eigenständige Gattungen [Contributions to the taxonomic revision of the genus *Lacerta* (Reptilia: Lacertidae). Part 1: *Zootoca, Omanosaura, Timon,* and *Teira* as full genera]. Salamandra 32(3):163–170.

Ambystoma tigrinum Complex Revisited



In a continuing quest to elucidate the phylogenetic relationships of the North American (U.S. and Mexican) tiger salamander complex, Shaffer and McKnight examined mtDNA sequence data derived from 840 base pairs of D-loop sequence. They suggest that the complex shows signs of abrupt lineage splitting less than 5 million years ago (younger than previous estimates based on allozymes and geology) and is characterized by generally low levels of differentiation among species. Recognition of monophyletic species is complicated by incomplete species boundaries (frequent hybridization between some very recently derived species) as well as by populations of nontransforming paedomorphic salamanders. They provisionally recognize eight primary lineages ("species") that only partially correspond to current taxonomy of this complex.

SHAFFER, H. B., AND M. L. MCKNIGHT. 1996. The polytypic species revisited: Genetic differentiation and molecular phylogenetics of the tiger salamander *Ambystoma tigrinum* (Amphibia: Caudata) complex. Evolution 50(1):417–433.

Basking Ecology of Razorback Musk Turtles

Basking razorback musk turtles (*Kinosternon carinatum*) were observed during replicated spotting-scope surveys in Mississippi and Louisiana. Razorbacks were seen more frequently and at more sites in the Pearl River drainage, and formed a higher proportion of the total number of turtles seen, than in the Pascagoula River drainage. Turtles usually basked in direct sunlight, often climbed high onto steeply angled branches of small diameter, and showed a propensity for basking on substrates not occupied by other species of turtles. Data for *K. carinatum* are compared with similar data for other kinosternid turtles.

LINDEMAN, P. V. 1996. Distribution, relative abundance, and basking ecology of the razorback musk turtle, *Kinosternon carinatum*, in the Pearl and Pascagoula River drainages. Herpetol. Nat. Hist. 4:23–24.

LETTERS TO THE EDITOR

CITES: Boon or Boondoggle?

WILLIAM W. LAMAR
School of Sciences and Mathematics, The University of Texas at Tyler
3900 University Boulevard, Tyler, Texas 75701-6699, USA
e-mail: 103223.306@compuserve.com

Regarding the excellent article by Gorzula on trade in dendrobatid frogs (Herpetol. Rev. 27:116–123), the issue of CITES-related problems and scientific activity begs amplification. I have never attended a CITES conference, but my colleagues have. We share the view that CITES and conservation authorities have been diffident towards the scientific community. While it may be true that CITES is, at its core, a monitoring effort, the fact remains that the treaty is varyingly, and frequently inappropriately, interpreted by each participating country. I disagree that this phenomenon be viewed as a separate matter, unrelated to CITES itself.

One country, for example, has prohibited export of a family of snakes simply because it appears on Appendix 2 of CITES. Another country decided that ALL exports of fauna (CITES and non-CITES alike), including museum loans, would require a $25 CITES permit, thereby effectively halting all scientific activity. Other examples abound.

Additionally, the inherent difficulty, expense, or even impossibility of obtaining CITES documentation has inadvertently created "black-market" status for many taxa named to the appendices. Thus, when *Vipera wagneri* was placed on the CITES list, its commercial value skyrocketed to US $1400 ... as predicted. Anguid lizards of the genus *Abronia* have also become costly collectors' items since their rumored impending CITES inclusion, precisely as predicted by Campbell and Frost in their 1994 revision (ironically, the very document that stimulated the interest of CITES). In examples such as this, the fact that CITES does not include means of protecting critical habitat is a detriment. I know of several cases in which scientists (myself included) have opted to remain silent regarding a species' critical status because CITES inclusion would only cause further harm.

While CITES was never intended to be a conservation treaty, it is my opinion that CITES officials and leading conservation organizations have chosen to ignore broad misinterpretations, perhaps on the premise that conservation by any means is justified. Also, if CITES is not a conservation treaty, then what is it? Far from simply monitoring wildlife "trade," its appendices carry restrictions. Presumably, a species deemed over-exploited would be advanced to a more exclusive appendix, or, that failing, the regional scientific authority would be called upon to make a special ruling before export could occur, thus rendering CITES an indirect conservation treaty. If such is not the case, then what exactly does CITES do?

Gorzula's explanation of oft-misunderstood terms is useful, but confusion remains. If, as he states, the CITES emphasis is on WILD populations, why all the monitoring of captive-bred transfers? Wouldn't they qualify as domestic? The term "trade" certainly is inappropriate, in spite of CITES' definition. Perhaps it should be changed to "traffic," as scientific activity hardly qualifies as trade when legitimately defined.

While there may be abundant reasons, as Gorzula states, for certain threatened or even endangered species not being included on CITES appendices, this has also added to a very confusing situation. I am aware of scientists who have meticulously and dutifully documented collections, complete with all requisite country-of-origin permits, only to arrive in the U.S., exhausted from the ordeal, and face legal action because a CITES Appendix II specimen is also U.S.A. Endangered. While CITES did not create this situation, they are part of it, and the often absurd lengths to which scientists must go to obtain their documentation helps lead to situations like that described above. Minimally, it would seem appropriate to tie Appendix status more closely to other lists bearing similar recommendations.

As Gorzula points out, CITES chose to ignore input from the scientific community regarding listing dendrobatids. Inasmuch as Gorzula's review supports the contention that listing these amphibians was premature, it would seem that the CITES secretariat should at least account for their reasoning. Who did they find to be more qualified than scientists to advise them?

Let's be candid about this, the world of conservation is basically about one thing: POWER. The scientific community has been penalized from the outset in this game because we lack the funds and the sort of lobby required in order to survive. If CITES and conservation authorities truly wish to clarify and refine the role of this cumbersome treaty, a good start would be to acknowledge some responsibility in this issue, advocate the critical work of the scientific community, use their considerable resources to educate the wayward regional management offices (or exclude them from the treaty), and begin to compile SEPARATE tabulations of scientific use of specimens instead of losing us in the blizzard of commercial trade data.

Scientific activity needs to be regulated separately in all countries, and CITES as well as conservation agencies could help to implement this. If, as Gorzula states, the total seven-year trade in dendrobatids would not fill a trash can, just think about the miniscule amount being used by the diminishing pool of scientists who provide the data used for CITES appendices and conservation organizations! We need a break, and it's long overdue.

REQUEST FOR SNAKE PHOTOGRAPHS AND REFERENCES

Whit Gibbons and Michael Dorcas are writing "Life History and Ecology of North American Aquatic Snakes" [negotiating contract with the University of Oklahoma Press] and plan to show examples of every color variant of species in the following genera: *Nerodia, Seminatrix, Regina*, and *Farancia*. Anyone willing to provide first-rate color slides on a temporary loan basis should contact Michael Dorcas by mail at Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29803, USA, or by e-mail at DORCAS@SREL.EDU. Any slides used will receive appropriate acknowledgment in the book.

We are also collecting all pertinent references for species of the aforementioned genera, and would appreciate receiving copies or citations of papers in press, unpublished Master's theses, or status reports. Copies should be sent to Dorcas at the address above.

A New Facsimile Reprint from the Society for the Study of Amphibians and Reptiles

LEOPOLD FITZINGER

NEUE CLASSIFICATION DER REPTILIEN

together with

ENTWURF EINER SYSTEMATISCHEN ANORDNUNG DER SCHILDKRÖTEN

LEOPOLD FITZINGER (1802–1884) IS ONE OF THE CLASSIC AUTHORS OF SYSTEMATIC HERPETOLOGY. FOR MOST OF HIS long career, he was a curator at the Naturhistorisches Museum in Vienna. His most important herpetological contribution was the naming of more than 70 genera that are in common and widespread use today. "Among the frogs we find such names as *Gastrotheca*, *Leptodactylus*, and *Pseudacris*; a salamander, *Salamandrina*, and the caecilian, *Ichthyophis*; several turtles, *Chelodina*, *Eretmochelys*, *Geochelone*, *Lepidochelys*, and *Psammobates*; and a large number of lizards, *Conolophus*, *Gonatodes*, *Mabuya*, *Psammodromus*, and *Stenodactylus*, and the snakes *Boiga*, *Chironius*, *Drymarchon*, *Elaphe*, *Lampropeltis*, *Malpolon*, *Psammophis*, and *Thamnophis*" (from the introduction by Robert Mertens).

Most of Fitzinger's generic names were proposed in just three of his publications: "Systema Reptilium," published in 1843 and reprinted by SSAR in 1973 (and still available: see below), and the two titles now being reprinted ("Neue Classification der Reptilien," published in 1826, and "Entwurf einer systematischen Anordnung der Schildkröten," 1835). In addition to these 70 generic names, Fitzinger designated type species (generotypes) for all genera of amphibians and reptiles recognized at the time, an action of critical importance in tying generic names to particular species. Moreover, other Fitzinger generic names have been resurrected recently — and others yet may be — as taxonomic revisions reveal new systematic arrangements.

***Specifications*:** 110 pages, one large foldout chart, portrait, 8.5 × 11 inches (21.6 × 28 cm), clothbound. To be published August 1997. ISBN 0–916984–41–9.

Prices: FITZINGER: "Neue Classification der Reptilien" and "Entwurf einer systematischen Anordnung der Schildkröten"
• SSAR members *before publication* . . . . . US$20 • Institutions and nonmembers $30
Also available: FITZINGER: "Systema Reptilium," 1843 (reprinted 1973), 128 pages, paperbound (few copies remain) . . . $15
Shipping: Cost per book, in USA . . . . . $3 • Non-USA $5

To order: Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Avenue, Saint Louis, Missouri 63103, USA (*telephone*: area code 314, 977–3916 or –1710; *fax*: 314, 977–3658; *e-mail*: ssar@slu.edu). Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to MasterCard or VISA (provide account number and expiration date). SSAR membership details and a complete list of all Society publications can be obtained on request to Dr. Aldridge.

Victoria, British Columbia, Canada V8W 2Y2

The Herpetological Collection at the University of Washington Burke Museum

The Thomas Burke Memorial Washington State Museum is located on the campus of the University of Washington in Seattle. Collections are curated by academic faculty jointly appointed to the Museum and the University. The Burke Museum is the Washington State museum of natural and cultural history, and is the only major natural history museum in the Northwest. The three divisions of Anthropology, Geology, and Zoology contain nationally renowned collections totaling over 3 million specimens, most of which are from the Pacific Northwest and Pacific Rim. The herpetological collection is part of the Zoology Division, which also includes curated collections of birds (over 60,000 specimens), mammals (41,000 specimens), spiders (75,000 specimens), butterflies (40,000 specimens), and other terrestrial invertebrates (30,000 specimens). The Museum also houses a Genetic Resources Collection that includes over 8000 specimens, mostly of avian tissues, stored at -80°C.

Prior to the establishment of the curated herpetological collection in 1985, the Museum housed several thousand unorganized and uncatalogued specimens, including an extensive series of garter snakes collected by W. B. Hebard in the 1940's. These specimens will be catalogued sometime in 1997. The current catalogue consists of over 2200 recently collected specimens, most of which are amphibians from western Washington. The curator is Dr. Keith B. Aubry, a research scientist with the USDA Forest Service. Dr. Aubry is an Affiliate member of the University faculty who curates the collection on a part-time basis. Virtually all of the specimens in the collection were preserved entire in formalin and are permanently stored in 70% ethanol. The collection is catalogued in digital form, which enables requests for information on holdings to be answered easily and quickly. The catalogued collection is available for use on site or by loan to researchers at other museums and educational institutions. Persons interested in viewing the herpetological collection should contact Keith B. Aubry by phone at (360) 753-7685, fax (360) 956-2346, or e-mail at kbaubry@aol.com.

There are several ongoing herpetological research projects being conducted in collaboration with faculty and students in the Wildlife Science Division of the College of Forest Resources, and with scientists at the Pacific Northwest Research Station of the USDA Forest Service. These include studies of amphibian communities in different structural stages of intensively managed forest stands; an experimental study of the effects on amphibians of varying the amount and pattern of green-tree retention in harvest units; an experimental study of the effects of introduced bullfrogs (*Rana catesbeiana*) on native red-legged frog (*Rana aurora*) populations; and a radio-telemetry study of the movement patterns of northwestern salamanders (*Ambystoma gracile*). The latter two studies are doctoral research projects being conducted by Michael Adams and Angela Stringer, respectively, under the direction of Dr. Stephen D. West. For more information on these projects, please contact Dr. West at the College of Forest Resources, (206) 685-7588.

The only other natural history museum in the Seattle area with a herpetological collection is the Slater Museum of Natural History at the University of Puget Sound in Tacoma, Washington, located about 30 min. south of Seattle. The Museum Director is Dr. Dennis R. Paulson, who can be reached at (206) 756-3798.

Herpetology at the University of British Columbia and University of Victoria

The last several years have seen a tremendous increase in the amount of herpetologically oriented research occurring at universities in British Columbia. Much of this growth has centered on the ecology of amphibians, especially in relation to anthropogenic disturbances of the landscape such as forestry. Despite a modest-sized native herpetofauna (17 species of amphibians, 12 of reptiles), there is much scope for research on these animals, including studies of their natural history in diverse environments. Most of the herpetological research in British Columbia is being done at the University of Victoria and the University of British Columbia.

Dr. Patrick Gregory has been doing herpetological research at the University of Victoria since 1973. The main focus of his work is the ecology and natural history of snakes, especially garter snakes, but he and his students also study various other species of amphibians and reptiles. Dr. Gregory's main current project is a long-term study of the population ecology of garter snakes at two sites in the British Columbia interior, begun in 1979. This study is beginning to yield significant data on longevity, growth, and frequency of reproduction in female snakes; it also has provided much data for recent work on geographic variation in reproductive traits of garter snakes. Other projects in various stages include: experimental analysis of the tradeoffs between feeding and thermoregulation in gravid snakes; a study of ontogenetic and size-related changes in diets of garter snakes; and manipulation of a rattlesnake den to minimize the impact of highway construction.

Dr. Gregory also has several graduate students and postdoctoral fellows working on a variety of projects. Heather Waye recently completed a Master's degree on the use of tail vertebrae from live snakes as a means of determining age of snakes for population studies. Master's students Lynn Norman and Christopher Shewchuk are studying the movement ecology of snakes (garter snakes and gopher snakes, respectively) using radiotelemetry. Trent Garner is doing a Master's degree on the occurrence of multiple paternity in garter snakes, using DNA fingerprinting. Pamela Rutherford has just begun a Ph.D. project on the costs of reproduction in alligator lizards.

Recently, Dr. Gregory's laboratory has become involved in more applied projects, such as studies of the effects of forestry practices on the distribution and abundance of amphibian species in northern Alberta; Master's students Patrick Garcia and Juanita Constible are undertaking that work. Postdoctoral fellows Dr. Robert St. Clair and Dr. Theodore Davis have begun similar studies in British Columbia on the rubber boa and western toad, respectively. All of these studies make use of radiotelemetry to determine patterns of habitat use by free-ranging animals. The work by Garcia and

Constible is being done in collaboration with Dr. Karl Larsen, a former student of Dr. Gregory's and now a faculty member at University College of the Cariboo in Kamloops, British Columbia.

Dr. Bradley Anholt is an experimental ecologist at the University of Victoria who uses anuran tadpoles as model organisms in some of his studies. Dr. Anholt is interested in the general question of how behavioral variation among individuals influences the dynamics of populations.

Most of the herpetological research at the University of British Columbia is being done in the Centre for Applied Conservation Biology and focuses mainly on amphibians. There are several major projects underway and only a glimpse of them can be given here. Drs. John Richardson and William Neill, aided by Karl Mallory, are conducting research on the natural history and demography of the Pacific giant salamander (*Dicamptodon tenebrosus*) at the northern limit of its range. The aim of the study is directed both at conservation of the species and at the more general question of how populations persist in fragmented landscapes. Dr. Neill's students are studying a number of other aspects of the ecology of these animals: Master's student Heather Ferguson is examining colonization of empty stream microhabitats and size-dependent movements of larvae; Master's student Barb Johnston is using radiotelemetry to study activity patterns, movements, home ranges, and habitat use of adults; and, undergraduate student Carolynn Stevenson is studying genetic relatedness among individuals at different spatial scales, using PCR analysis of satellite DNA.

Dr. Richardson also is collaborating with Dr. Fred Bunnell on a study of tailed frogs (*Ascaphus truei*) that has similar goals to the work on giant salamanders. Tanya Wahbe is completing her Master's degree with Dr. Bunnell on the habitat associations of larval tailed frogs and the influences of forestry practices on larval populations. Dr. John Carlson and his laboratory are lending their expertise in molecular genetics to complement the work being done on ecology and conservation of tailed frogs; in particular, they are examining genetic diversity among populations. Elke Wind is doing a Master's degree with Dr. Bunnell and Dr. Ann Chan-McLeod on the effect of forest fragmentation on wood frogs (*Rana sylvatica*) in north-central Alberta. Linda Dupuis is involved in a number of projects with Dr. Bunnell, including: the distribution and abundance of tailed frogs in British Columbia; the effects of various silvicultural treatments on amphibian communities in Sechelt; the importance to amphibian communities of riparian habitats along fish-free streams of managed stands and old-growth forests. Finally, Dr. Bunnell is working with Glenn Sutherland and Isabell Houde in a study of the persistence of amphibians in managed forests.

Other studies being done at the University of British Columbia include the following: relative abundance and habitat use of amphibians in wetlands and hydroriparian zones on Vancouver Island (Dr. Chan-McLeod); the effects of forest harvest on the habitat requirements of long-toed salamanders (*Ambystoma macrodactylum*) (Master's student Christine Ferguson with Drs. Tom Sullivan and Walt Klenner); the effects of aquatic toxicology on various amphibian species (Karen Pettit in the Dept. of Animal Science).

Clearly, there is no shortage of herpetological activity, especially of the ecological variety, at British Columbia universities. The most interesting aspect of all this, of course, is what people are actually finding. Unfortunately, space constraints do not permit a recounting of the results of all these various projects, so you'll have to keep on eye on the journals to learn that. Many thanks to Bill Neill, John Richardson, and Tanya Wahbe for providing information on goings-on at UBC.

We regard species as genetically discrete (i.e., separate and independent) populational entities, whereas subspecies are taken as genetically non-discrete (confluent) populational entities. That distinction we regard as axiomatic despite arguments to the contrary (e.g., Barton and Hewitt 1985).

The non-discrete nature of subspecies is evident from their definition as geographic segments of any given gonochoristic (bisexually reproducing) species differing from each other to a reasonably practical degree (e.g., at least 70–75%), but to less than totality. All subspecies are allopatric (either dichopatric [with non-contiguous ranges] or parapatric [with contiguous ranges], except for cases of circular overlap with sympatry); sympatry is conclusive evidence (except for cases of circular overlap) of allospecificity (separate specific status). Parapatric subspecies interbreed and exhibit intergradation in contact zones, but such taxa maintain the required level of distinction in one or more characters outside of those zones. Dichopatric populations are regarded as subspecies if they fail to exhibit full differentiation (i.e., exhibit overlap in variation of their differentiae up to 25–30%), even in the absence of contact (overlap exceeding 25–30% does not qualify for taxonomic recognition of either dichopatric populations or of parapatric populations outside of their zones of intergradation). Phenotypic adjustment to differing environmental conditions through natural selection is likely the primary factor in divergence of parapatric subspecies, and undoubtedly is involved in some dichopatric subspecies. The founder effect and genetic drift are involved more in the latter than in the former.

In spite of the objective validity of subspecies, they have been seriously questioned with increasing vigor for over 40 years, beginning most prominently with Wilson and Brown (1953; but see Wilson 1994). More serious threats have come in recent years from proponents of the newly propounded Phylogenetic and Evolutionary Species Concepts.

The inherent non-discrete nature of subspecies, combined with their long, justifiable history of acceptance as an essential part of biosystematics, has perforce been a problem in the context of phylogenetic inference that logically deals with discrete entities. The impasse has led to unjustified rationalizations in the form of either outright rejection of subspecies or of forcing them into a higher rank (species) for which they are fundamentally not qualified as here (and commonly) defined.

Proponents of the Evolutionary Species Concept dispose of subspecies, for the most part, by disregarding them completely as a component of the biotic classification system (Frost 1995; Frost et al. 1992; Simpson 1961; Wiley 1981, 1992; Wilson and Brown

1953). Typically, in the application of that concept, subspecies are examined critically for their distinctiveness, and those that do not rigorously qualify in that context are not accepted taxonomically.

By contrast, proponents of the Phylogenetic Species Concept have generally acted in concordance with the views espoused by Barton and Hewitt (1985), by elevating valid subspecies to species rank despite their non-discrete nature (Baum 1992; Cracraft 1992; Davis and Nixon 1992; Eldredge and Cracraft 1980; Nelson and Platnick 1981). Doing so leaves the term subspecies applicable only to minor geographic variation that usually would not be accepted as taxonomically significant, as, for example, clinal segments and pattern classes (e.g., Cracraft 1992:104). Were subspecies so relegated, we too would join Cracraft in rejecting them.

We hold that neither rationalization is justified or necessary. The rational policy is to continue to accept subspecies as a legitimate and essential part of biotic classification, but at the same time to exclude them from phylogenetic analyses that are logically limited to discrete, fully distinct entities. In that context, subspecies considerations cannot conflict in any way with species concepts and phylogenetic constructs based upon them. The subspecies category is already properly accommodated in the current edition of the International Code of Zoological Nomenclature, and its recognition, as in the past, is supported by biologists worldwide (Hawksworth et al. 1994).

The Rationale for Exclusion of Subspecies from the Phylogenetic Species Concept.—Current interpretation of phylogeny requires that, in phylogenetic classification, populations maintain evolutionary independence if they are to be recognized as taxonomically distinct units. Therefore, parapatric subspecies cannot be embraced in phylogenetic philosophy and practice because they have no phylogeny in the sense of a history of separate identity. On the contrary, dichopatric (= non-parapatric allopatric) populations may individually be regarded as full species, if sufficiently well differentiated (i.e., infallibly diagnosable, with fixed character differentiation), or, if not, as tertiary subspecies. Degrees of distinction (one or more characters) and the extent of intergradation differ widely in nature, and their interpretation in some cases inevitably results in subjective assessment of ranking that is equally inescapable in the application of any species concept. That fact is no argument against the validity of subspecies as nomenclatural entities, although it is a strong argument for excluding subspecies from phylogenetic analyses.

The Problems Created by Subspecific Exclusion from All Classification.—The emergence of a guiding phylogenetic (historical) philosophy in systematics was regarded by Frost et al. (1992:46) as "the biggest paradigm shift in systematics in the last 140 years."

There is good reason for universal acceptance of the basic tenets of the Evolutionary or Phylogenetic species concepts in proper contexts. It is critical, however, to recognize that these contexts are not all-inclusive. The common perception of classification as conforming with and representing phylogenetic hypotheses must be superimposed upon the even more basic responsibility of reflecting biodiversity. Systematics and classification therefore have two functions, here referred to as taxonomic and phylogenetic. It is not sufficient that classification only reflect phylogeny; it must also reflect biodiversity by accounting for all "kinds" of animals, and subspecies as well as species constitute "kinds."

The dual responsibility of classification to reflect both phylogeny and biodiversity has long been recognized (e.g., Simpson 1961:27–28). To limit the scope of these dual responsibilities of classification by exclusion of subspecies, through their distortion by elevation to species rank, or through abandonment, in order to reflect phylogeny at all classification levels, is unwarranted. Alternatively, having two classifications, one for each role (phylogenetic and biodiversal), would be chaotic.

Frost et al. (1992), in stating the case for Phylogenetic Classification, argued forcefully for abandonment of subspecies, and Frost later (1995) implemented his views in a novel way. So tempting has been that move toward simplicity that it has spawned widespread neglect of comprehensive studies of the geographic variation that often delineate subspecies. Thus two problems are constituted by subspecies in present contexts: their validity in the first place, and, if recognized at all, their integration within a phylogenetic system of classification.

Validity of Subspecies.—Despite arguments against admission of subspecies in taxonomy, that category has consistently proven useful and illuminating. Nevertheless, as pointed out by Frost et al. (1992), even such a staunch supporter as Mayr on occasion (1982) wrote deprecatingly about the nature and value of the subspecies category. In a more recent work, Mayr and Ashlock (1991:41) noted that "some of the best proofs of the occurrence of evolution have emerged from the study of polytypic species taxa. To convert the nominal species of all groups of animals into well-delimited polytypic species taxa is therefore one of the major tasks of taxonomy." Nevertheless, they (ibid.:53) remarked that the "new systematics" of today recognizes "the subspecies as a category, not as an evolutionary unit."

It is perfectly true that subspecies are not independent evolutionary units, as previously noted in the context of phylogenetic systematics. But, it is equally true that they are products of evolution and, where valid, are recognizably different taxonomic entities. To exclude valid taxonomic entities from classification misrepresents fact and neglects a level at which a major part of evolution is occurring at all times and at varying rates, although it is little studied, understood, and appreciated in most groups of animals. Such studies, however, "have provided the best available evidence for the process of allopatric speciation, the frequent origin of evolutionary novelties in peripherally isolated populations, and numerous intermediate stages in the evolutionary process, thus elucidating previously inexplicable discontinuities" (Mayr and Ashlock 1991:41).

The initial and most enduringly influential opponents of subspecies were Wilson and Brown (1953), who argued that "It is more informative to focus on the traits and not on the subspecies that might be concocted from them" (Wilson 1994:208). But, by 1994, Wilson (*loc. cit.*) later confessed that "Some populations can be defined clearly with sets of genetic traits that do change in a concordant, not a discordant manner. Furthermore, the subspecies category is often a convenient shorthand for alluding to important populations even when their genetic status is ambiguous."

Indeed, perhaps the most powerful argument against the validity of subspecies is that intraspecific geographic variation commonly involves several or more characters varying independently either kaleidoscopically or discordantly, in part due to selection pressures differing with each environmental variable. It is nevertheless true that consistent (at the 70% level or better) recognizability of subspecies is evident within some species. Occasionally only one character qualifies, but usually a suite is involved. In multivariate contexts, subspecies are definable by the suite of characters that explains the largest adequate percentage of the variance of the data-set, thus minimizing the "noise" produced by the variance of other characters. Hence the spectre of an infinite number of subspecies is in reality a delusion. Blanket rejection of subspecies, even on the basis of deficient or defective analysis, denies their possible, if not proven, validity, under the criteria here stated, as *consistently recognizable* geographic entities. Alterna-

tively, elevation of them to full species rank denies their non-discrete nature. Neither alternative is justified.

Although defense of subspecies has been dismissed by some phylogeneticists as old-fashioned and outmoded, the fact remains that comprehensive and objective studies of geographic variation, especially in widely distributed (but also some narrowly distributed) species, often reveals the presence of distinctive geographic segments that eminently qualify for taxonomic, even if not phylogenetic, recognition (e.g., Grismer et al. 1994; Taylor et al. 1994). Rejection of subspecies on grounds of phylogenetic incompetence, or difficulty of analysis, or of burdensome museum administration, is spurious and fails to recognize fact. We view the current popularity of disregarding subspecies as an uncritical attitude.

Rejection of subspecies as non-genetic ecotypes unless proved to be genetic adaptations is unwarranted, inasmuch as dichopatric species of any closely knit species group are subject to the same uncertainty. Parsimony dictates acceptance that allopatric populations that are phenotypically distinguishable at a taxonomic level have their differences genetically based unless or until proved otherwise.

Rejection of the subspecies concept inevitably leads in many instances to unjustified elevation to species rank of taxa that should rank as subspecies. Careful consideration of rank alternatives for different allopatric populations is severely discouraged if one of those alternatives no longer exists.

Although the subspecies category has on occasion been abused in the past, the same is true of the species and every other nomenclatural category. Abuses particularly exist where populations are subject to predominantly discordant geographic variation or linear clinal variation, when segments are nevertheless recognized taxonomically. A comprehensive (rather than piecemeal) study of geographic variation within the species should precede the delineation and naming of subspecies, or should be the ultimate test of subspecies that have been erected piecemeal. The use of multivariate statistical procedures can provide approaches that are reasonably objective and not dependent on preconceptions about taxonomic membership. Nonetheless, the discriminatory power of such methods depends critically on the quality of the characters being analyzed and, in addition, the adopted standard for level of differentiation required for taxonomic recognition. Multivariate analyses (Thorpe 1987) are useful techniques for substantiation of subspecific validity, with revival of the now generally neglected 75% (or similar) rule (idem:7).

The conclusion most emphatically is that subspecies, even on strictly *theoretical* grounds, are a vital component of taxonomic practice, should be retained as an acceptable option where warranted, merit inclusion in classification, and are properly accommodated in current rules of nomenclature. They are of importance not only in systematics but also in other theoretical disciplines such as biogeography and evolution itself.

In addition, from a *practical* point of view and quite apart from theoretical validity, the subspecies category is vital to balanced conservational, medical, nutritional, and other applied biologies. In such considerations, the recognition of geographical segments, particularly of widely distributed species, is of fundamental importance because they may represent differentiated gene pools that can be substantially different in important ways (e.g., Glenn and Straight 1985, 1987). Although the focus of phylogenetic systematics is properly on the established directions of genetic change, it would be tragic if that focus were allowed to lead to the abandonment of studies of intraspecific geographic variation that are of such vital importance in the understanding, assessment, and conservation of biodiversity.

In that context, Ryder (1986) proposed recognition of "evolutionarily significant units" (ESU), alternatively "evolutionarily significant populations" (ESP), where they exist among the subspecies of any given species. That concept was endorsed and expanded by Vane-Wright et al. (1991) and Vogler and DeSalle (1993), although the terms ESU and ESP, as applied by these authors, are inappropriate and misleading, as noted by Cracraft (1991); in reality they were dealing with "*conservationally*" significant units ("CSU"). Nevertheless the focus by these authors upon subspecies and their relative merit for conservation was thoroughly justified. Unfortunately, Cracraft (*op. cit.*), observing that in his opinion all ESU's are phylogenetic species, concluded that "Under this concept, subspecies have no special ontological [i.e., incipient species] status and can be abandoned."

As an example of the importance of subspecies in conservational considerations, *Sceloporus undulatus garmani*, an arenicolous, terrestrial, cursorial, striped subspecies with reduced semeions (ventral color patches) appears to have become extinct, or nearly so, in parts of its range on the plains of eastern Colorado. On the contrary, another, very different, larger, cross-barred subspecies with well-developed semeions, *S. u. erythrocheilus*, remains common on the eastern slopes of the Rocky Mountain foothills, where it leads a scansorial life on trees and, mostly, rocks. The two subspecies occur within a few kilometers of each other in some areas, but no intergradation occurs and even gross sympatry is possible. Different conservational measures may be required for these two subspecies, but they would be difficult or impossible to prescribe or implement if no subspecies were recognized. Entire subspecies populations could become extinct if attention were directed to the species as a whole, which could be regarded as basically healthy. In cases such as this, elevating the constituent subspecies to species rank does not always provide a solution. For example, in the case cited, there is a complete, although stepped, continuity between the two taxa: *S. u. garmani* intergrades to the south with *S. u. consobrinus*, the latter with *S. u. tristichus* to the west, and that in turn with *S. u. erythrocheilus* to the north—a typical circular approximation of range, if not overlap.

Although the practical constraints of conservation efforts may require restriction of attention to the species rank, elevation of subspecies as here and as commonly defined to species rank would be a disservice to limited conservational efforts aimed at preservation only of major genetic resources.

In defending the concept of subspecies, i.e., maintaining them in classification much as in the past, we do not see them as of universal existence among organisms. In many groups they appear never to have evolved, no doubt for various reasons, including extreme vagility. We merely insist that in some groups they are readily evident, and that where this is the case, they merit taxonomic recognition, serving as they do as vehicles for the development of testable hypotheses regarding the causes, proximate and ultimate, for variation and its geographic stabilization.

Integration With Phylogenetic Classification.—The second problem posed by recognition of subspecies in the era of phylogenetic emphasis is perhaps of relatively minor concern, since it can be resolved by context and requires no operational modification of long-established custom. Where the context and goals are strictly phylogenetic, subspecies obviously should be disregarded. Where the context and goals are taxonomic to the lowest level, subspecies should be recognized, as they have been over the past few decades. They are entities already incorporated into taxonomic and nomenclatural procedure, as indicated by the present edition of the International Code of Zoological Nomenclature and its predecessors as early as the 1905 Regles. Biologists worldwide also

reiterate their intent to maintain recognition of subspecies in the future (Hawksworth et al., 1994). The studies by Grismer et al. (1994) and Reichling (1994) demonstrate the compatibility of subspecies with phylogenetic systematics. There is no conflict, hence no need for exploration of alternative nomenclatural systems.

Intraspecific Taxonomic Derivation.—In the context of Phylogenetic Classification, as currently interpreted, "intraspecific phylogeny" approaches an oxymoron, and in effect has been widely so interpreted in recent discourses. Yet derivational patterns are commonly discernible among the subspecies of polytypic species, as noted by Thorpe (1987:3), who commented that intraspecific "patterns of geographic variation *can* [italics ours] be caused by both current ecological conditions and historical factors, i.e. phylogenesis." The evolutionary phenomena culminating with attainment of species rank are also involved in patterns of subspeciation. However, we suggest that intraspecific evolutionary patterns evident among subspecies be designated as taxogenetic (taxon-forming), rather than phylogenetic (derivational), in order to avoid what might be regarded as an oxymoronic application of the latter term.

Indeed, Olmstead's (1995) proposal for distinguishing "apospecies" (with one or more uniquely derived characters) and "plesiospecies" (with a unique combination of characters, none derived) can logically be extended to subspecies. Thus, "aposubspecies" (e.g., *Sceloporus undulatus erythrocheilus* with unique lip/throat reddish coloration; *S. u. belli*, with fused gular semeions) can be distinguished from "plesiosubspecies" (e.g., most other subspecies of *S. undulatus*).

Summary.—The nature and evolutionary implications of biodiversity is a central challenge of modern biology. To appreciate the full extent and significance of biodiversity, we assuredly need to recognize and have names for the discrete, unquestionably phylogenetically competent taxa belonging to the categories of species, genera, families, etc. We need also to recognize and have names for the non-discrete but genetically distinctive geographic segments of species, even if they are regarded as phylogenetically incompetent (i.e., derivationally non-committal). Both concerns are essential to analyses of diversity. It perforce follows that to pursue such analyses properly a comprehensive and unified system of nomenclature is essential. Our system must include all these groups, both discrete and non-discrete.

Subspecific nomenclature is more than a step in the study of natural variation. It is a tool for conveying information about major patterns of variation within species, flagging opportunities for causal analyses. A subspecies name draws attention to a geographic segment of a species that in some way is recognizably different, and beyond that, it provides information about diversity to a variety of disciplines from genetics and ecology to conservation biology. The study of intraspecific variation could go on without the use of subspecific nomenclature, but a tremendous lot of biotic diversity would be obscured and made almost inaccessible by the absence of names. Workers *will* fail to notice biological diversity without names.

Acknowledgments.—We are much indebted to Drs. Richard Etheridge, Michael C. Grant, Harry Greene, Anna Goebel, Arnold Grobman, Robert G. Jaeger, Richard Olmstead, Jeremy D. D. Smith, Stephen G. Tilley, Wolfgang Wüster, and an anonymous reviewer for vital input, although their endorsement of the views here expressed is not implied.

Published by the Society for the Study of Amphibians and Reptiles

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

THE CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES (CAAR) represents one of the most important long-term cooperative activities undertaken by the American herpetological community. The *Catalogue* is issued as loose-leaf accounts of taxa (each 1–17 letter-size pages in length). Each account, authored by a leading herpetologist, serves as a complete and current summary of the knowledge of each taxon. Further, the CAAR is not restricted to those taxa occurring within the United States, but covers the entire Western Hemisphere (North, Central, and South America, as well as the Caribbean Basin). The *Catalogue of American Amphibians and Reptiles* sets the standard for archival taxonomic publications and has been emulated by biological societies worldwide.

The *Catalogue* is issued by subscription; 20 accounts/year. All back issues (1–640), special CAAR binders, indexes, and systematic tabs are also available.

Each CAAR account includes:

- Synonymy
- Content, definition, and diagnosis
- Comprehensive literature review
- Distribution map(s)
- Nomenclatural history
- Remarks
- Etymology

Many accounts also include:

- Photographs (some in color)
- Illustrations of key characters
- Taxonomic keys to species or subspecies
- Audiospectrograms

de Sá. 1995. *Hyla albopunctata*. Account 602

Because of the evolutionary and ecological importance of the mimetic relationships the members of the genus *Pliocercus* share with those of *Micrurus*, the appearance of a revision of the former genus should be a cause for celebration. On the contrary, however, the publication of the long paper "Species-group taxa of the false coral snake genus *Pliocercus*" by Hobart M. Smith and David Chiszar (1996) raises so many troubling issues for herpetologists, especially those specializing in systematics, that the impulse to celebrate is quickly stifled. The purpose of our paper is to examine these issues and to suggest means by which the members of the herpetological community can deal with them.

Circumventing peer review and its consequences.—The major issue associated with the appearance of Smith and Chiszar (1996) is one we have examined previously (McCranie and Wilson 1979). It involves the appearance of systematic research in outlets that do not utilize peer review. The Smith and Chiszar publication herein under review was published by Ramus Publishing, Inc., which also produces the herpetoculturist publication *Reptile & Amphibian Magazine*. Nowhere in the *Pliocercus* document is there any indication that anyone besides Erica Ramus, the editor and publisher, reviewed this work before its appearance in print. She is credited in the Acknowledgments for "... editing and masterminding publication of this review." No one who has worked on the systematics of *Pliocercus* in the past (e.g., Brian Crother, Harry Greene, Roy McDiarmid, Jay Savage) was sent a copy of the manuscript for review. As astounding as this lack of peer review may seem, it is even more so when one considers the breadth of the departure Smith and Chiszar have made in their taxonomic conclusions from those of the most recent prior revisers, Savage and Crother (1989). We are tempted to conclude that peer review was circumvented by Smith and Chiszar precisely because their conclusions differ so startlingly from those of other recent workers (Greene and McDiarmid 1981; Savage and Crother 1989; Wilson and Meyer 1985). In fact, our contention is that the issues and problems discussed in the remainder of this review are so serious that had this work been subjected to the normal course of peer review by qualified herpetologists, it would never have seen the light of publication day.

Our position is that scientific papers *must* be subjected to peer review, and that such is *especially critical* when the paper deals with systematics, including the naming of new taxa. We cite the following as a case in point concerning what can happen when peer review is eschewed. In 1992, Smith and Chiszar described a new genus and species of boid, *Boella tenella*, based on a specimen without locality data. These authors, however, reasoned it to have come from Oaxaca, México. Later the same year and in the same journal, Wallach and Smith (1992) demonstrated that the single known specimen upon which the new genus and species were based is actually a specimen of the well-known *Epicrates inornatus* of Puerto Rico. Both the latter lengthy paper and the original description would not have required publication if Smith and Chiszar had taken the obvious step during their research to run the undocumented specimen through some of the well-known keys to boids that exist in the literature. Wallach and Smith (1992) even point out that the specimen keys out to *E. inornatus* in Schwartz and Henderson (1985). More to the point, had the editor of the *Bulletin of the Maryland Herpetological Society*, Herbert S. Harris, sent the paper to Bob Henderson to review, the first paper would have headed for the "round file" and the second never would have been conceived. Such ill-conceived, poorly researched, and unreviewed work is a waste of limited publication resources available to herpetologists and all other scientists. That such waste is avoided is one of the reasons that peer review exists.

Given, however, that it is becoming increasingly easy to circumvent peer review in systematic and other types of research in herpetology, we strongly suggest that the major herpetological societies in this country make this burgeoning trend an agenda item for the next earliest business meetings and produce resolutions in opposition to this trend. This issue may be intransigent enough, moreover, that the matter should be presented to the International Commission on Zoological Nomenclature for a ruling.

Questionable systematics technique.—One of the most striking outfalls of the lack of peer review of the Smith and Chiszar *Pliocercus* revision is the major departure these authors make from accepted analytical procedure in systematics research. The accepted approach to building a classification and associated nomenclature is to gather data on a given allotment of specimens, survey the literature about the creature(s) being studied, analyze the data in some appropriate fashion, and construct a set of conclusions based on this analysis. The conclusions then are supposed to lead to a classification with phylogenetic meaning and an attendant nomenclature for the taxa recognized.

Smith and Chiszar certainly carried out the first step. They examined 516 specimens, collecting data on scalation and color pattern. These data, however, are subjected to an incredibly superficial (and, therefore, misleading) analysis confined to the work's introduction and consisting of, at most, six pages, which are also occupied by three distribution maps and one scale drawing. The survey of the literature appears to be reasonably complete (after all, this is one of Smith's fortes), but there is only limited discussion of the history of that literature, and the most important piece of literature on the systematics of *Pliocercus* prior to the one under review, Savage and Crother's (1989) revision, is dispensed with in the first sentence of the introduction. Otherwise, this important paper is referred to on p. 29 (information on status of holotype of *P. euryzonus*), p. 30 (reference to a range map for the lower Central American and South American populations), p. 34 (information on variation and range of Smith and Chiszar's concept of *P. dimidiatus*), and p. 84 (in connection with the discussion of anatomy of *Pliocercus*). As such, the arguments presented in Savage and Crother's work are not critically examined to indicate the need to depart from the established taxonomy. The bulk of the work consists of the taxonomic conclusions, which take the form of the classic account. For all practical purposes, their approach jumps from step 1 (gathering the data) to step 4 (erecting taxonomic conclusions), with only passing attention being given to step 2 (discussion of significance of prior literature) and step 3 (data analysis). Thus, we are asked to accept Smith and Chiszar's conclusions at *virtual face value*.

As a consequence, there is no analysis of character variation outside the context of the authors' taxonomic conclusions. The assumption is made on their part that character variation is only important if such variation is "taxonomically significant." Thus, the authors make the assumption that no other conclusions might derive from analysis of the same data set and, furthermore, that no

other analysis can be conducted on a given data set than the one they have conducted. The implication is: "Here's our analysis and conclusions: take them, or if you wish to leave them, do the work from scratch." Wilson and Meyer (1985) have discussed this procedural problem at length. Again, competent peer review would have easily exposed Smith and Chiszar's procedural anomalies.

The "cart before the horse" procedural anomaly.—The curious technique of data analysis has created for Smith and Chiszar the most serious flaw in their conclusions, which by itself should have kept this paper from being published in its present form. In the section entitled "The relation of mimicry to taxogeny in *Pliocercus*," they indicate that understanding the impact of mimicry on evolution in *Pliocercus* must await unraveling the taxonomy of the genus. Thus, they state (p. 77) that "... the absence of a basic understanding of the taxonomy of *Pliocercus* has been an insurmountable obstacle to a sound appraisal of the extent and nature of mimicry between that opisthoglyphous, mildly venomous genus and the sympatric, highly venomous, proteroglyphous genus *Micrurus*." They, however, at least in part, belie their own statement by adding that "Mimicry is ... a product of adaptive flexibility, which occurs at the sacrifice of phyletic stability. The extent to which each phenomenon has influenced phylogeny in *Pliocercus can be given meaningful consideration* [emphasis ours] only in the context of reasonably sound concepts of taxonomy in the genus, *heretofore lacking* [emphasis ours]." In our opinion, however, the reverse is the case. Reasonably sound concepts of taxonomy in *Pliocercus* can only be produced by meaningful analysis of the extent to which mimicry has influenced phylogeny in this genus. That Smith and Chiszar have not recognized this obligation is reflected not only in their statements, but in the organization of their work as well. The relatively short treatment (four and one-half pages) of mimicry follows the taxonomic section rather than preceding it. In addition, the discussion in this section is relatively superficial and uniformative, compared, for example, to treatments in Greene and McDiarmid (1981) and Savage and Crother (1989).

Given that we can now agree that mimicry does occur in *Pliocercus*, then such a relationship represents a selective agent for populations of *Pliocercus* and *Micrurus* alike and is indicative of the progress of coevolution. In most cases, snake systematists are at a loss to even posit the selective pressures impinging on the character variation they document. With *Pliocercus* and its venomous models, we have a comparatively easily understood system to study. Both genera exhibit brightly colored patterns that to a creature capable of color vision such as ourselves are obvious and require from us only eyes, paper, pencil, and some basic analytical skills to decipher. Smith and Chiszar, on the other hand, have the idea that a classification and nomenclature should be established first, that then can be used to unravel the mimetic relationships. Thus, they are mired in a hog wallow of misunderstanding. The hog, however, creates the wallow, not the reverse. The mimetic relationship between *Pliocercus* and *Micrurus* is surely one of the selective agents that has shaped the phylogeny of these snakes, which phylogeny we attempt to codify with our classifications and nomenclatures. The classifications and nomenclatures do not create the selective pressures. Nevertheless, working out the details of this mimetic relationship will occupy researchers for some time, given its complexity.

The deductive-inductive sleight of hand.—Smith and Chiszar's taxonomy of the genus *Pliocercus* depends on a curious attempt to pass off an invalid inductive argument as a valid deductive argument. In nonformal logic, a deductive argument is one in which if the premises are true, then the conclusion is necessarily true (Dreisback and Cavalier 1985). In an inductive argument, the claim is that if the premises are true, then the conclusion is probably, but not necessarily true (Driesback and Cavalier 1985). This is the logical conceit that forms the linchpin that fastens Smith and Chiszar's analysis to their conclusions.

In the introduction (pp. 17–18), the authors point out that "It was obvious at the outset that some of the populations with broad black rings (*P. dimidiatus* and *P. andrewsi*) seemed to maintain their integrity even where sympatry with narrow-ringed populations occurs. Yet in the absence of other differences, e.g., in scalation, no evidence short of documentation of breeding true (woefully lacking) could still the suspicion of polymorphism of a single species." They go on to say (p. 18) "Of critical significance, therefore, was the discovery in the course of this review that indeed one of the broad-ringed populations (here referred to as *P. bicolor*) possesses a unique feature of scalation, found in no other populations of the genus, but found in every one of its own populations: fusion of the rear infralabial ... with the adjacent, rear labiogenial." The integrity of this distinction is indisputable. So, the premise of this argument is true. Smith and Chiszar, however, go on to draw an important and disputable conclusion from this premise. They indicate (p. 20) that "The significance of the categorical distinction between the separate (A type, throughout most of the genus) and fused (B type, *P. bicolor* only) condition of the rear infralabial is that it provides *sound evidence* [emphasis ours] that pattern types can indeed be taxonomic indicators." This conclusion is not supportable in our opinion and makes of this an invalid inductive argument. Unfortunately, Smith and Chiszar attempt to make of it a valid deductive argument, as is indicated by what follows. These authors proceed to note that "Certainly conversion from the A type to the B type confers no isolating benefit of itself. But with its *assurance* [emphasis ours] that the distinct, homogeneous pattern-type named *P. bicolor* is a distinct species, the hypothesis *becomes reasonable* [emphasis ours] that at least some of the other, distinct, homogeneous pattern-types are also valid species *despite* [emphasis ours] the absence of known confirmatory scale differences." Finally, they conclude that "Thus we regard *P. euryzonus*, *P. psychoides*, *P. dimidiatus*, *P. wilmarai* and *P. andrewsi* as additional valid species, and the geographic variation in *P. elapoides* and *P. bicolor* itself takes on *taxonomically meaningful significance* [emphasis ours]."

Essentially what Smith and Chiszar are saying is that if they can link one scale variation, no matter how minor, to one of the pattern conditions in this genus, then some (why not all?) of the other pattern conditions in the genus can also be regarded as "taxonomically significant," i.e., have formal names applied to them. Thus, the invalid inductive argument is passed off as a valid deductive argument and used as the basis for a string of thus defenseless taxonomic decisions. The use of this logical fallacy by Smith and Chiszar as the sole criterion for departing from the Savage and Crother schema is illustrative of the extremes to which traditional systematics techniques can be pushed to justify whatever conclusions are most congruent with one's systematics philosophy.

Chimeric systematics-biogeographic philosophy.—Because of the predictive and self-corrective value of cladistic systematics, it is in an ascendant position relative to traditional evolutionary systematics. It is understandable, therefore, that in the interest of having their work published, some traditional systematists might resort to trying to create a chimera of the techniques and terminology of the two approaches to systematics. This is what Smith and Chiszar have done with their *Pliocercus* work.

In attempting to divine the nature of their technique, however, we are left to deciphering their conclusions, inasmuch as there is no methods section in the paper. Smith and Chiszar introduce the cladistic terms plesiomorphic and apomorphic on page 25, with

no indication how they arrived at such applications. The accepted norms of cladistic technique, including choice of outgroups, character-state determination and polarization, and cladogram construction and statistical analysis thereof are nowhere to be found. As such, there is no basis for the assignment of plesiomorphic or apomorphic status to any of the characters they examine. Furthermore, there is no support for designation of taxa as least, less, more, or most derived. As an extension, there is also no basis for their biogeographic discussion, especially the idea that the "taxogeny" of *Pliocercus* has been primarily shaped by three "dispersal events." The rambling house of cards Smith and Chiszar have constructed, thus, falls into a heap, leaving no basis for either their taxonomic or their biogeographic conclusions.

More in the continuing saga of the subspecies.—During the 1950's, the subspecies concept was discussed in detail, especially in the pages of the journal *Systematic Zoology.* Proponents and detractors jousted with one another for years. When the dust settled, adherents to both views still existed. In herpetology, however, the subspecies has been largely abandoned. The concept, however, has been given a sound drubbing by Wilson and Brown (1953), Savage and Heyer (1967), and Wilson and Meyer (1985). In their *Pliocercus* work, however, Smith and Chiszar have made extensive use of subspecies.

Their adherence to what we consider to be an outmoded systematics concept is defended in interestingly disparate fashion in two publications in the same issue of the *Bulletin of the Maryland Herpetological Society.* In one paper (Smith, Wallach, and Chiszar, 1995), the authors state that "We subscribe to a positive vision of the place of subspecies in zoological taxonomy, involving no conflict with the Phylogenetic Species Concept, partially on ground expressed by Smith and White (1956), and partially because of the importance of subspecies in considerations of conservation and protection. *Properly understood* [emphasis ours], they do constitute genetically unique populations, and as such, even if not effectively closed, merit as much concern and recognition as other genetically unique populations. Abandonment of such a long-accepted and *vital* [emphasis ours] category as subspecies is neither warranted nor necessary, even in a strictly phylogenetic classification, to which they can be regarded as an adjunct, without change of name or treatment" (p. 209).

Invocation of the subspecies concept is not necessary to express concern for the conservation and protection of the diversity of life. The definition of biodiversity, after all, includes diversity at all levels, genetic, specific, and ecosystemic (Wilson 1992). Biodiversity decline is an environmental problem that attacks all levels of the diversity of life on Earth.

The other defense is provided by Smith, Ramírez-Bautista, and Chiszar (1995), who state that "We suspect that much of the resistance in general to the recognition of subspecies is a product of *unwillingness to deal with the tedious detail involved in demonstrating their reality* [emphasis ours]. Other reasons exist, of course, but a reluctance to undertake or give credence to the value of the extraordinary effort required to demonstrate the existence of genetically distinct, reliably identifiable populations should not be under estimated or condoned" (p. 201). These statements border on being insulting to those biologists who have argued against the use of subspecies, implying that they are simply *too lazy* to underwrite the "extraordinary effort" necessary to "demonstrate their reality." Moreover, these layabouts are not even willing to acknowledge the value of such effort undertaken by others. This is not an argument likely to prove compelling to other workers.

The homoplagiarism tarantella.—There must have been some anxious moments in the respective offices of Smith, Chiszar, Ramus, and Harris as the reviewed work and Issue 2 of Volume 32 of the *Bulletin of the Maryland Herpetological Society* (BMHS) went to their respective presses. The Smith and Chiszar work includes an account of *Pliocercus wilmarai*, a taxon described in a paper by Smith et al. (1996), cited as in press! The latter work appeared in the above-mentioned issue of the BMHS. Fortunately, Smith and Chiszar narrowly missed committing homoplagiarism by two weeks. The BMHS issue is dated 30 June 1996 and the Smith and Chiszar work 15 July 1996. Although we suspect this instance was carefully orchestrated to avoid homoplagiarism, our experience has been that one should await the appearance of a new name in print *before* using it in a subsequent work. The obvious solution to this situation would have been to publish the original description of *P. wilmarai* in the work under review, crediting it to Smith, Pérez-Higareda, and Chiszar. Examples of this type of procedure are in Smith (1965) and Wilson (1987).

Taxogeny versus phylogeny.—Smith and Chiszar provide biology with a new term in this work, viz., taxogeny. On page 20, they attempt to explain the term in its adjectival form, as follows: "Another scale character of minor taxogenetic (a term introduced here to avoid usage of the term 'phylogenetic' in reference to subspecies, whereas 'taxogenetic' can be used in that context, although also embracing the restricted concept of 'phylogenetic') significance, although independently not diagnostically useful, are the extremes in number of ventrals and caudals, which diminish with populational derivation." As we write this review, we still feel at bay in our attempts to understand this statement, as well as the included definition. Apparently, Smith and Chiszar wish to "restrict" the use of the term "phylogenetic" to taxa other than subspecies and have invented the word "taxogenetic" to encompass the subspecies and all other taxonomic levels. Why this is necessary is not explained, except to provide a means to circumvent use of the word "phylogenetic." Why it is necessary to do so is not explained either. We suspect it is because the term phylogeny is usually defined as "the evolutionary development and history of a species or higher taxonomic grouping of organisms" (American Heritage College Dictionary 1993) and, thus, would not strictly involve consideration of the evolutionary history of subspecies. Thus, we now have a term for aficionados of subspecies to use to refer to the sum of evolutionary development. A slight broadening of the definition of the term phylogeny, if deemed really necessary, would have accomplished the same end, resulting in taxogeny being stillborn.

Summary.—The issues and problems in the Smith and Chiszar work discussed above are sufficient, we believe, to render their systematic conclusions and the resulting classification and nomenclature invalid. We suggest, therefore, that students of Latin American herpetology revert to the use of the Savage and Crother taxonomy, until such time as a suitably conducted systematic revision demonstrates that another taxonomy is justifiable. Circumventing peer review to allow appearance of systematic work of the caliber produced by Smith and Chiszar in the work under review is not likely to be viewed as either desirable nor acceptable by the herpetological community.

Acknowledgments.—We would like to thank our peer reviewers, R. Powell, J. M. Savage, and K. L. Williams, for their perceptive comments on our work.

**Author to whom all correspondence should be addressed.*

Post-hatching parental care has often been assumed to be nonexistent in squamate reptiles (e.g., Wesolowski 1994). However, recent studies have suggested limited parental care in some species of lizards (see Shine 1988 for review). Many of these examples concern egg brooding behavior where the female protects her clutch of eggs from desiccation or thermal extremes (Somma and Fawcett 1989; Vitt and Cooper 1985), or may remove spoiled eggs from the nest (Groves 1982; Somma 1989). Few reports exist of post-hatching parental care (e.g., Somma 1987).

In this note we report observations on an apparent case of extended post-partum parental care in the Mexican knob-scaled lizard (Xenosauridae:*Xenosaurus newmanorum*). *Xenosaurus newmanorum* is a viviparous species, with a gestation period of approximately 11–12 months, a biennial reproductive cycle, and a litter size of 1 or 2. Members of this species live in cracks in rock walls in a tropical cloud forest, and exhibit marked sexual dimorphism in head size and body size. We studied the natural history of *X. newmanorum* in a marked population in San Luis Potosí, México. Individuals were marked and measured approximately monthly from February 1994 to November 1995.

We observed adult female *X. newmanorum* living in cracks with neonates in the months of August, September, and October. This behavior differs from two other species of *Xenosaurus* that we have observed in the field (*X. grandis* and *X. rectocollaris*). Neonates of these species were found in close proximity to adult females, but we have never seen adults and neonates living together in the same crack. Ballinger et al. (1995) reported the solitary behavior of *X. grandis*, and the occurrence of male-female pairs in *X. newmanorum*. We have also observed solitary behavior in *X. rectocollaris*.

Six adult female *X. newmanorum* that were pregnant in the months of June and July were observed to live in the same crack with up to two hatchlings after parturition. Of 12 neonates observed between August and October (1994 and 1995), nine were living in the same crack as a female that was pregnant in the months of June and July. In three cases, one neonate was living with a single female in the crack. In three other cases, two neonates were living with a single female in the crack. In all the adult female-neonate pairs or groups, the adult female was always at the front of the crack, and the neonates were behind the adult females. Indeed, it was often necessary to check each crack occupied by an adult female carefully in order to see a neonate.

The association between neonates and adult females appears to be relatively long lasting. One marked adult female-neonate pair lasted from 26 August 1995 to 6 October 1995 (41 d). Another pairing between a marked pregnant adult female and a marked juvenile lasted from 27 May 1995 to 6 October 1995 (132 d). However, we did not observe the same associative behavior (i.e., female in front of juvenile in crack) with this larger juvenile (SVL = 78 mm, TL = 150 mm, BM = 7.0 g).

Neonates were never found in association with adult males during the study period, even though males were found in nearby cracks. However, male-female pairs of *X. newmanorum* can be found in the month of December. During the time that these male-female pairs form, pairs can be seen living in close proximity to other pairs, with up to three male-female pairs occupying cracks within a 1 m^2 area. Therefore, the lack of male-neonate pairs does not appear to be a function of solitary behavior in males, and also indicates that the female-neonate pairs are not simply random associations of adult lizards with young lizards.

Our observations on female-neonate associations suggest that they may have a basis in parental care, presumably an anti-predator function; however, this is only one of several possible explanations. Females may protect their offspring by placing themselves between potential predators and their offspring. Another possible explanation of the female-neonate positions (e.g., female on outside of neonate) may be that neonates can get farther into the crevice than the larger females. However, there does not appear to be an association between lizard size and crevice size in *X. newmanorum* (J. A. Lemos-Espinal, G. R. Smith, and R. E. Ballinger, unpubl. data). These observations should be seen as preliminary since we can only assume that the adult females and neonates are parent and offspring. However, it seems likely that they are mother and offspring since individuals have relatively small home ranges and are relatively sedentary. Recent experiments have suggested that some lizards may have the ability to discriminate their own offspring from unrelated juveniles (Bull et al. 1994), which, along with our observations, imply that post-hatching parent-offspring interactions in lizards may be more common than previously assumed.

Acknowledgments.—We thank C. M. Bull, W. Card, J. Rettig, and an anonymous reviewer for reading and commenting on an early version of this note. Field assistance was provided by S. Sanoja-Sarabia and local residents. Financial support was provided by Proyecto CyMA-UIICE, UNAM, and the University of Nebraska School of Biological Sciences. Some logistic assistance during manuscript preparation was provided by the Kellogg Biological Station, Michigan State University.

**Author to whom all correpondence should be addressed.*

Diet and feeding ecology of snakes of the genus *Vipera* in Europe have been studied in detail in several areas of their range (Baron 1992; Bea et al. 1992; Luiselli and Agrimi 1991; Sebela 1980). Methods involved in studying food preference and diet of snakes usually involve analyses of stomach contents (e.g., Luiselli and Agrimi 1991; Shine 1986) or feces (Reinert et al. 1984); in only a few cases (Shine 1986) have stomach and fecal analyses been carried out at the same time.

In this note we present the results obtained from the analysis of both stomach contents and fecal matter from a *Vipera aspis* population (Monney 1990; Saviozzi 1994). This work was designed to compare the usefulness and precision of both methods when studying the diet of snakes.

The study area was at Arnino, 8 km SW of Pisa and 2 km E from the Ligurian coast, in the "Parco Naturale di Migliarino-S. Rossore-Massaciuccoli," western Tuscany, central Italy (43°39'45" N, 10°17'30" E). The 3.9-ha study site was largely cultivated. During 1990–1994, we obtained 30 meal samples from 76 captured specimens (48 females, 26 males, and 2 juveniles). A recent meal was determined by palpation of the ventral surface. Prey samples were obtained by forced regurgitation or with Kjærgaard's (1981) method. Fecal samples were collected within a few hours by holding the snake in captivity. Samples were preserved in 70% alcohol until examination and are now in the collection of ingesta of the Natural History Museum of the University of Pisa.

The identity of regurgitated prey items was determined using Toschi and Lanza (1959) and Toschi (1965) or by comparison with specimens preserved at the Museum. Mammal hairs from fecal samples were examined microscopically (Debrot et al. 1982). When necessary, hairs were compared to a reference collection at the Museum. Shapes and patterns of the cuticular scales varied greatly along each hair, but all these features were quite constant within the same taxon (Debrot et al. 1982). All the morphologically different hairs (different taxa) coming from a single fecal sample were examined. Isolated teeth were also used for identification, according to Chaline et al. (1974).

The 30 meal samples collected contained 33 identifiable prey items, of which 8.6% (N = 3) were lizards and 91.4% (N = 30) were mammals (Fig. 1). Among the latter, rodents constituted 84.4% (N = 25) and insectivores 15.6% (N = 5). The number of prey types (represented by genera) identified from the two methods (4 vs. 8) did not differ significantly (binomial test, $p > 0.05$; Siegel 1980). However, there was a significant difference in the number of prey items obtained from fecal analysis (23) compared to stomach contents (10) ($c^2 = 5.12$, 1 df, $p < 0.05$; Siegel 1980). These results suggest that stomach content analysis of field-captured snakes may underestimate prey diversity, especially if the sample sizes are small. Our failure to obtain lizard prey from fecal samples is likely attributable to the very low number of fecal samples from juvenile snakes—those most likely to feed on lizards.

The frequency of *V. aspis* with identifiable stomach contents ranges from 35% to 49% of the snakes examined (Luiselli and Agrimi 1991; Sebela 1980; Slip and Shine 1988). Fecal matter was present at similar frequencies in the intestinal tract of snakes that had not recently fed (Saviozzi 1994; Sebela 1980; Slip and Shine 1988). This relationship enabled us to verify not only the correct determination of prey taxa from stomachs using the most abundant hairs from fecal samples, but also to check if other prey types were present in the intestinal tract of the same specimen. We found as many as three prey species in a single snake. Evidence of prior meals may remain within the intestine for periods up to several weeks.

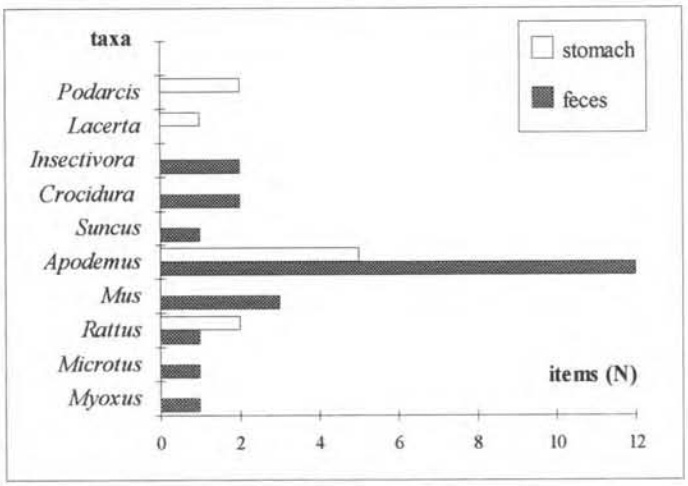

FIG. 1. Prey composition of *Vipera aspis*. Legend: Family Gliridae: *Myoxus* = *Myoxus glis*; Family Muridae: *Microtus* = *Microtus savii*; *Rattus* = *Rattus* sp.; *Mus* = *Mus domesticus*; *Apodemus* = *Apodemus sylvaticus* and *Apodemus* sp.; Family Soricidae: *Suncus* = *Suncus etruscus*; *Crocidura* = *Crocidura* sp.; Insectivora = Insectivora indeterminate; Family Lacertidae: *Lacerta* = *Lacerta viridis*; *Podarcis* = *Podarcis sicula*.

Ontogenetic variation in prey composition of *V. aspis* has been reported; reptiles are rare in the diet of adult snakes but comprise a higher percentage of prey taken by juveniles (Bea et al. 1992; Luiselli and Agrimi 1991). The types and frequency of prey taxa reflects geography, site characteristics, and faunal composition of the study area (Luiselli and Agrimi 1991; Monney 1990). However, it is evident that the temporal aspects of prey frequency, or the estimation of energy gain/loss ratio during feeding activity of a snake population, can be studied by analysis of the both stomach contents and fecal matter (Baron 1992; Luiselli and Agrimi 1991; Monney 1990; Shine 1986). Fecal analysis is time consuming. However, it may provide a more complete taxonomic sample of the prey consumed, especially in the case of small samples or when short-term studies are planned (Saviozzi 1994; Zuffi and Saviozzi, unpubl.).

Acknowledgments.—Particular thanks are due to F. Papi for providing logistical support, and to H. K. Reinert for his review of the manuscript.

20TH ANNUAL
ALL FLORIDA HERPETOLOGY CONFERENCE

Co-sponsored by The Florida Museum of Natural History and The Gainesville Herpetological Society

19 April 1997
The University of Florida, Gainesville, Florida

Registration: $14 per person (before 12 April); $16 per person.

Speakers include: David Auth, William Lamar, Brian Bowen, Ken Dodd, Richard Funk, Elliot Jacobson, Jim Jarchow, Wayne King, Lee Grismer, Erica Ramus, Kathy Love.

Also featured: Captive Breeders Exhibit; Herp Art, Books, and Jewelry; Florida Live Turtles Exhibit; Egg Incubation Workshop.

For information or to register, contact: *David Auth, Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, or call (352) 392-1721.*

Blanding's Turtle Specimens from the Turner Farm Archaeological Site, North Haven, Maine

ARTHUR E. SPIESS

Animal bone remains from archaeological sites provide excellent data for determining past range and relative abundance of many vertebrate and invertebrate species (Graham and Mead 1987; Klein and Cruz-Uribe 1984; Semken and Falk 1987). Maine's coastal shell middens are a superb storehouse of information pertaining to hunting and fishing success by Native American inhabitants for the last few thousand years because the discarded shell neutralizes Maine's acidic soil and preserves bone (Spiess 1993). Many coastal shell middens have faunal evidence of occupation during all seasons of the year; thus we know that portions of the coast were not abandoned at any particular season (Sanger 1996).

The Turner Farm site is on North Haven Island, Maine, USA, which, when paired with Vinalhaven, forms the largest island land mass in Penobscot Bay (Fig. 1). The Turner Farm site contains the longest uneroded record of coastal habitation yet excavated in the northeastern United States (Bourque 1995), and the most detailed faunal record so far analyzed (Bourque 1995; Spiess and Lewis 1995, in press) with over 30,000 vertebrate specimens identified. Occupation at Turner Farm began about 5200 years ago with episodic use lasting until arrival of Europeans.

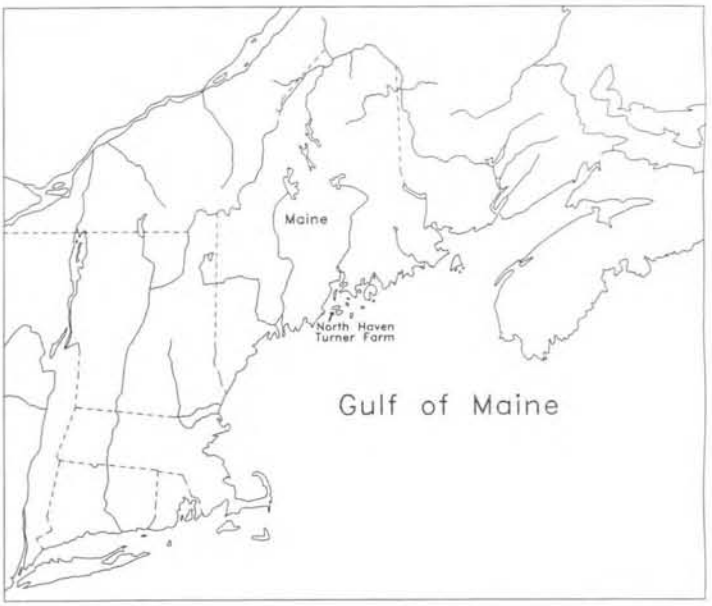

FIG. 1. Location of the Turner Farm Site.

Turtle bone from the site was identified using comparative material in the Faunal Laboratory at the University of Maine, Orono, and the use of an extensive turtle comparative atlas for archaeological identifications (Sobolik and Steele 1996). The majority of

bones were identified as carapace fragments from large and medium-sized snapping turtles (*Chelydra serpentina*) and one nuchal fragment of an emydid species, probably of the genus *Clemmys* (wood and spotted turtles). The most complete specimen (Fig. 2) is a large partial carapace reconstruction from 12 bones, identified as *Emydoidea blandingii* (Blanding's turtle). In addition, three other bones were also identified as belonging to *E. blandingii*.

The partial carapace reconstruction includes bones from the left second to the right sixth peripheral, plus fragments of three pleurals (Fig. 2). Eleven of these twelve bones were found in a single occupation layer ca. 4000 years old (catalogue number D-1158). The twelfth specimen (catalogue number C-252) was the left second peripheral recovered from disturbed "plowzone" deposits which overlie the site. The recovery of one bone from this individual from an upper stratum indicates that digging in the site, possibly by later prehistoric Native American inhabitants, disturbed and scattered the specimen.

FIG. 2. Reconstructed specimen of *Emydoidea blandingii*.

Publications documenting turtle remains from New England archaeological sites have not been common. French (1986) reports the first identification of *E. blandingii* from an archaeological context: site 17.22 on Hog Island, Muscongus Bay, Maine, from deposits dating sometime between 2500 and 500 years old. These remains include five reconstructed *E. blandingii* carapace fragments, which came from a turtle with an approximate carapace length of 22.5 cm. Eleven *E. blandingii* bones were also identified from a sample of 599 turtle bones from Concord Shellheap in Massachusetts from deposits radiocarbon dated to 4660 years old (Rhodin 1992, 1995).

Therefore, Turner Farm is the third archaeological site in New England from which *Emydoidea blandingii* has been recovered. Blanding's turtle is a common species in the Turner Farm deposits, more common than all other turtle species except for *Chelydra serpentina*. In discussing the disjunct distribution of the redbelly turtle, Rhodin (1992:29) comments that the faunal evidence "suggests at least partial extirpation at the hand of prehistoric man." His statement seems based upon the fact that the species was being harvested by Native Americans, and is no longer present near the few archaeological sites in Massachusetts where it has been found to occur. His sample, however, lacks internal time depth differentiation. With the Turner Farm sample of *E. blandingii*, we come to a different conclusion. The species was harvested by Native Americans, true, but it survived for at least 3500 years in the local herpetofauna. The most recent identification dates just before European contact (ca. 500 yrs B.P.). Rather than extirpation at the hands of Native American hunters and gatherers, the Turner Farm data seem to support the hypothesis that Blanding's turtle survived modest harvest pressure for millennia.

Acknowledgments.—We thank Richard T. Will, J. Alan Holman, and Anders G. J. Rhodin for reviewing the manuscript. Funding for Turner Farm faunal analysis was provided by National Science Foundation grant 13035 to Bourque and Spiess, and by the Maine State Museum and Maine Historic Preservation Commission.

The genus *Sauromalus* is composed of the two continental species, *S. obesus* and *S. australis*, whose collective range is throughout the desert regions of the southwestern United States and northwestern México, including several islands in the Gulf of California (Murphy and Ottley 1984; Shaw 1945). Additionally, there are five insular endemics in the Gulf of California: *S. ater*, *S. hispidus*, *S. klauberi*, *S. slevini*, and *S. varius* (Murphy and Ottley 1984; Shaw 1945). One of these, *S. varius*, is known only from Isla San Esteban in the Midriff region (Fig. 1). Lowe and Norris (1955) reported *S. varius* from Isla Alcatraz off the coast of Sonora; however, Robinson (1972), Case (1982, 1983), and Grismer (1994) considered this a hybrid population resulting from aboriginal introductions and to be composed of a genetic cross involving *S. varius*, *S. hispidus*, and *S. obesus*. Lowe and Norris (1955) also reported *S. varius* from Isla Cholludo (an islet off the southern end of Isla Tiburón) based on a possible sight record from R. S. Felger of an individual entering a burrow. This report was followed by Soulé and Sloan (1966), Murphy (1983), and Murphy and Ottley (1984) although it was never verified.

We report here a new insular population of *Sauromalus varius* from a small, rocky, satellite island known as Isla Roca Lobos, lying 0.25 km west of Isla Salsipuedes, which represents a range extension of ca. 35 km due west of Isla San Esteban (Fig. 1). Isla Roca Lobos is approximately five ha in area and 20 m in elevation. It has xeric-adapted vegetation of the Central Gulf Coast phytogeographic region (Wiggins 1980) dominated by *Opuntia fulgida*, *O.* cf. *burrageana*, *Pachycereus pringlei*, *Stenocereus gummosus*, *Oligomeris linifolia*, *Atriplex barclayana*, *Nicotiana trigonophylla*, and *Physalis crassifolia*. *Sauromalus varius* is listed as an endangered species (Dodd 1980) and conservation and management plans are currently being implemented (Lawler and Jarchow 1986; Lawler et al. 1994). The chuckwallas on Isla Roca Lobos represent the second confirmed wild population of *S. varius* and should play a meaningful role in conservation efforts. However, in order for this population to be incorporated effectively into a management plan for *S. varius*, the morphological and genetic variation relative to the Isla San Esteban population should be understood adequately. The maintenance of small populations and the nature of their variation is of special interest because an understanding of such variation may help clarify the necessary levels of genetic diversity needed to maintain viable populations in the wild and in captive breeding programs. Therefore, the intent of this paper is to (1) compare the morphology of the Isla Roca Lobos lizards to that of Isla San Esteban, and (2) discuss the origin of this population. The results of a genetic study, currently in progress, will be reported elsewhere.

On 31 March 1994, two of us (CRM and BHB) discovered, captured, and released three adult female *S. varius* on the east side of Isla Roca Lobos in association with rock outcroppings. Three of us (BDH, CRM, and LLG) returned on 5 July 1995 and observed 14 adults, seven of which were captured and morphological data recorded (see below). Each lizard was photographed (LACM PC 1268–1274) and released.

Meristic counts follow the terminology of Shaw (1945) with some modifications (Table 1). These include (1) number of ventral scales between the gular fold and vent (VENTRL); (2) number of dorsal scales in a single head length measured from the

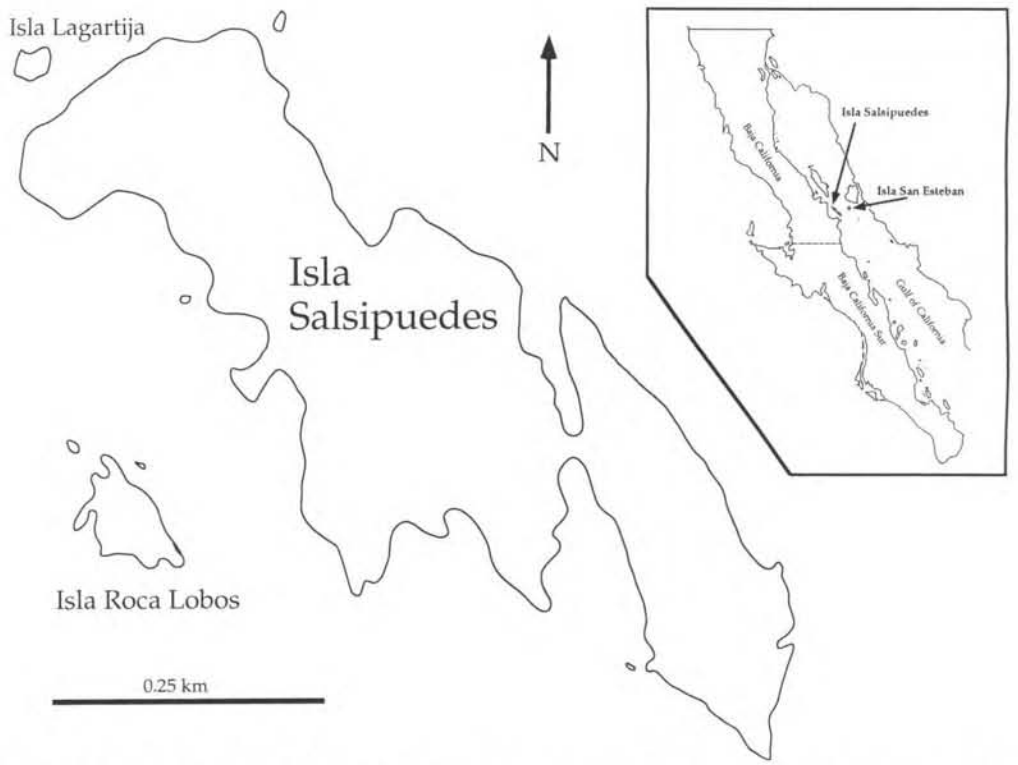

FIG. 1. Location of islas San Esteban, Salsipuedes, Lagartija, and Roca Lobos in the Gulf of California, México.

anterior margin of the external auditory meatus to the tip of snout (DORSAL); (3) number of caudal scales in an annulus two head lengths posterior to the vent (CAUDAL); (4) number of brachial scales encircling the thickest part of the upper arm (BRACHL); (5) total number of femoral pores (FEMPOR); (6) total number of supralabial scales (SUPRAL); (7) total number of infralabial scales (INFRAL); and (8) number of rostral scales differentiated from the adjacent supralabials by being slightly larger (ROSTRL).

Student *t*-tests (95% confidence interval) run on StatView SE v.1.03 (Feldman et al. 1988) compared the seven individuals from Isla Roca Lobos to 19 museum specimens from Isla San Esteban (Appendix I) for each meristic character. The populations were tested for sexual dimorphism and interpopulational differences. A principle component analysis (PCA) run on Bio∑tat II (Pimentel and Smith 1985) was performed using six of the eight meristic characters (Fig. 2) and 16 of the 19 individuals from Isla San Esteban. The three excluded individuals could not be scored for rostrals, supralabials, and infralabials. Dorsals were excluded from the PCA due to significantly different means ($P < 0.05$) between males and females. In order to include dorsal counts, the analysis would have to have been split according to sex, lowering the overall sample size, and affecting the statistical reliability of the results. Rostrals were excluded because they were not normally distributed.

The degree of morphological variation in the Isla Roca Lobos population was similar to that of *Sauromalus varius* from Isla San Esteban (Fig. 2; Table 1). Student *t*-tests revealed no significant differences between the mean of the meristic counts for the two populations (Table 1). In addition, no significant sexual dimorphism was detected, with the exception of the dorsal scale counts for the Isla Roca Lobos population. This character was therefore compared for each sex between the two populations and no significant differences were observed (Table 1).

The PCA was consistent with the *t*-tests, indicating broad overlap between the two populations (Fig. 2). In fact, the sample from Isla Roca Lobos displayed as much variation as that found in the Isla San Esteban population (Fig. 2; Table 1) with 76.1% of this variation being distributed over the first and second principal component axes (Fig. 2). The dispersion along the first principal component axis (61.7%) is primarily the result of the variation in ventral scale counts.

The lack of morphological divergence between these two populations suggests that the Isla Roca Lobos population may have had a recent origin. We believe it is unlikely that the presence of *Sauromalus varius* on Isla Roca Lobos represents a natural colonization because of the island's geographic location. Isla Salsipuedes lies between islas San Esteban and Roca Lobos (Fig. 1) and would more than likely serve as a barrier to direct overwater dispersal. No evidence of chuckwallas was found on Isla Salsipuedes or an additional satellite island (Isla Lagartija) lying 0.25 km to the north. The nearest chuckwalla population is that of *S. hispidus* on Isla San Lorenzo Norte (= Isla Ánimas), which is part of the same geological block as Isla Salsipuedes and its satellite islands (Gastil et al. 1983). Based on these factors, the presence of *S. varius* on Isla Roca Lobos is best characterized as anomalous and is likely the result of a human introduction. There are numerous proposed cases of introductions of *Sauromalus* onto small islands. The most notable involves the sea-faring Seri Indians who were known to eat chuckwallas obtained during long, sea turtle hunting expeditions (Bahre 1983; Case 1982; Felger and Moser 1985; Malkin 1962). Grismer (1994) proposed that chuckwallas had been transported and released onto smaller, near-shore islands because small island size would facilitate their recapture.

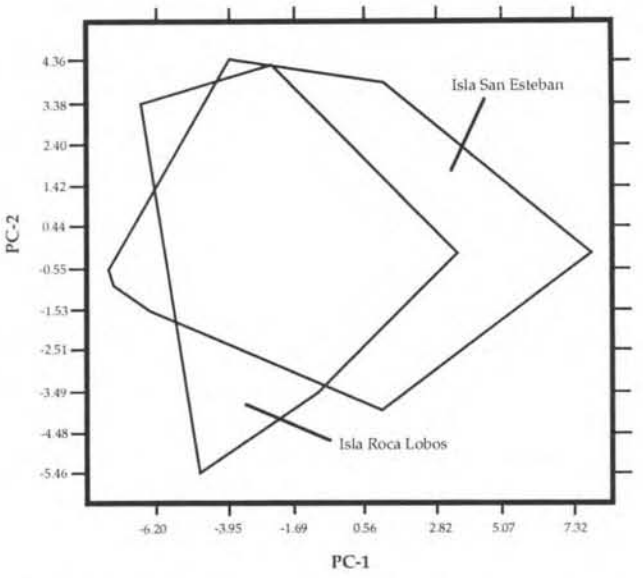

FIG. 2. Principal componant analysis (PC1 and PC2) accounting for 76.1% of the observed variation.

Another, less publicized means of colonization, is by way of the experimental relocation of chuckwallas by scientists into non-native areas (e.g., Case 1982; Sylber 1985). It remains a possibility that the Isla Roca Lobos population represents an experiment to explore the effects of colonization and subsequent evolution of an insular population.

Although we do not condone the practice of introducing species into areas in which they do not naturally occur, especially fragile and sensitive insular ecosystems, this particular introduction may actually contribute to the conservation of *Sauromalus varius*. Its presence on Isla Roca Lobos could prove important to this species' survival. Close monitoring may allow biologists to determine the minimum number of animals necessary to prevent inbreeding depression in wild and captive populations.

Acknowledgments.—We thank R. Bezy, K. Beaman, G. Bradley, and E. Gergus for comments on the manuscript, T. Oberbauer for his efforts in plant identification, and S. Curtis and D. Fehlmann for assistance in the field. We extend our sincere gratitude to L. Banta for funding and support of research in the Midriff islands. Our good friend and colleague, A. Reséndez, helped in arranging transportation to the island. Special thanks is extended to J. Vindum and J. Gauthier at the California Academy of Sciences and G. Pregill at the San Diego Natural History Museum for the loan of specimens, R. Bezy for cataloging photographs, and the Department of Natural Sciences, Loma Linda University and the Department of Biology, La Sierra University for additional funding and support. This research was conducted under a scientific research permit (no. A00 700[2]-05621) issued by Instituto Nacional de Ecología, Dirección General de Aprovechamiento, Ecológico de los Recursos Naturales, Dirección de Flora y Fauna Silvestres in México City to Dr. E. Mellink of Centro de Investigaciones Científicas y Escuela Superior, Ensenada, México.

Lip-Flaring in Thamnophiine Snakes and its Possible Association with Feeding on Soft-bodied, Sticky Prey

ALAN DE QUEIROZ
Section of Ecology and Systematics
Cornell University, Ithaca, New York 14853, USA
Current Address: University Museum and Department of EPO Biology
University of Colorado, Boulder, Colorado 80309, USA
e-mail: dequeiro@stripe.colorado.edu

Responses to predators often involve the use of traits that originally evolved as feeding adaptations (Greene 1988). In snakes, biting and discharging the gut contents are obvious examples of this phenomenon (Greene 1988). Here I consider a more subtle potential example in thamnophiine snakes. Specifically, I report lip-flaring as a response to a perceived predator in the northwestern garter snake, *Thamnophis ordinoides*, and note that the distribution of this behavior among thamnophiine species suggests a connection to feeding on soft-bodied, sticky prey.

While collecting *Thamnophis ordinoides* in the vicinity of Requa, Del Norte Co., California, USA on 19 June 1987, I observed three individuals of this species showing lip-flaring behavior when handled. This behavior consisted of dorsolateral movement of the supralabial scales and underlying tissue (hereafter referred to as the "lip") on both sides of the head.

About one month later, I recorded the behavior of 25 *T. ordinoides* (including the three just mentioned) under controlled conditions in an environmental chamber at Cornell University in Ithaca, New York. The 25 snakes included 17 from the Requa site, seven from Crescent City, Del Norte Co., California, and one from the junction of Lobster Creek and the Rogue River, Curry Co., Oregon, all collected 18–19 June 1987. While in captivity, snakes were individually housed in plastic shoeboxes, kept on a 14L:10D light cycle, and fed earthworms and/or fish. The trials took place between 1030 and 1100 h EDT at a temperature of 24.5°C. For each trial the snake was held at midbody and then tapped lightly five times on the head. Immediately following this procedure, I closely examined the snake for lip-flaring. Seven of the 25 snakes (one from Crescent City and six from Requa) showed distinct lip-flaring, i.e., with the distortion of the dorsal outline of the head readily apparent. Five other snakes showed slight lip-flaring, including two that flared only the right lip. Broken down by sex, five of 16 females, one of five males, and one of five individuals that were not sexed showed distinct lip-flaring. Nine of the 25 snakes have been preserved as vouchers (CU 11819–11825, 12461, and 12463), including two that flared the lips (CU 11819 and 11823).

Certain individuals are apparently more prone than others to flare the lips. Of the 17 snakes examined carefully for the behavior both in the field and in the lab, the three that flared the lips at the time of capture were a subset of the six that showed the behavior in the lab trials reported above. Furthermore, in subsequent lab trials on these same 17 snakes (de Queiroz 1992), four of five that flared the lips were ones that had shown this behavior in the earlier trials.

Among thamnophiine snakes, lip-flaring occurs commonly in *Storeria occipitomaculata* (Gosner 1942; A. de Queiroz, pers. obs.) and has been reported in one case in *Virginia valeriae* (Conant 1938). I have also observed distinct lip-flaring in two *Thamnophis sirtalis* from Tompkins Co., New York. I have not observed distinct lip-flaring in extensive field and lab observations of 14 other

species of *Thamnophis* (de Queiroz 1992) and know of no other reports of this behavior in the considerable body of work on thamnophiine antipredator behavior (e.g., Arnold and Bennett 1984; Godley 1982; Herzog et al. 1992; Scudder and Burghardt 1983).

At least among thamnophiines, there appears to be an association between lip-flaring and feeding on prey that are sticky and soft-bodied (i.e., lack a hard skeleton). *Thamnophis ordinoides* feeds primarily on earthworms and slugs (Fitch 1941; Gregory 1978, 1984), *S. occipitomaculata* seems to eat slugs almost exclusively (Gilhen 1984; Semlitsch and Moran 1984; also see references in Rossman and Myer 1990), and *V. valeriae* feeds largely on earthworms (Ernst and Barbour 1989 and references therein). Although *T. sirtalis* feeds on a wide variety of prey, in New York earthworms make up the majority of its diet (Hamilton 1951). Assuming that the above species are the only four thamnophiines that flare the lips, current hypotheses of phylogenetic relationships among thamnophiine genera (Robin Lawson, pers. comm.) and among species of *Thamnophis* (de Queiroz and Lawson 1994) suggest four independent originations of the behavior. This and the fact that the majority of thamnophiine species do not feed primarily on soft-bodied prey (Arnold 1981; Mushinsky 1987; Rossman et al. 1996) suggest that the association between lip-flaring and diet is not due to chance. Of course, attributes that are correlated with diet, rather than diet per se, might be the cause of the association (for example, with the exception of *T. sirtalis*, all of the above species are small). Also, it does not appear that lip-flaring and a diet of soft-bodied, sticky prey necessarily occur together. For example, the behavior does not seem to be present in *T. brachystoma* and *T. butleri*, which are both earthworm specialists (Rossman et al. 1996), and it does occur in some snakes and other squamates (e.g., the Asian lycodontine *Cyclocorus*—Ron Crombie, pers. comm.; some agamids—Greene 1988) that do not feed on such prey.

Whether lip-flaring is used in feeding is unknown; thus explanations for the possible association of lip-flaring and diet are purely speculative. Hobart Smith (pers. comm.) has suggested that certain kinds of soft-bodied prey (such as earthworms) might be more easily swallowed without using the teeth. In this case, flaring the lips might function to move the teeth out of the prey's path down the throat. Although in lip-flaring, the maxillae do not seem to move in complete concert with the lips (thus, lip-flaring exposes the teeth), it may be that the maxillae do move dorsolaterally to some extent. Another possible explanation is that pulling the lips away from the maxillae might help remove mucus from the teeth. In any case, I am speculating here that lip-flaring in response to predators occurs only following initial selection of the trait for some feeding function.

The possibility of a causal relationship between lip-flaring and feeding on soft-bodied, sticky prey is presented here as conjecture based on suggestive, but by no means definitive, comparative evidence. Verifying the evolutionary association requires observations of many more taxa, and support for the proposed explanation of such an association requires functional studies of the feeding mechanics of the species in question.

Acknowledgments.—The observations reported here were facilitated by an Andrew Dickson White Fellowship from Cornell University and by a Pre-doctoral Fellowship and a Doctoral Dissertation Improvement Grant (BSR 8715037 to F. H. Pough) from the National Science Foundation. I thank Sean de Queiroz for help collecting snakes; Hobart Smith, Harry Greene, and Ron Crombie for observations on lip-flaring; and Hobart Smith and Joana Silva for comments on the manuscript.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in volume 27, number 2 (June 1996).

CAUDATA

AMBYSTOMA CALIFORNIENSE (California Tiger Salamander). **BURROWING ABILITY.** It is assumed that ambystomatid salamanders are generally poor burrowers and rely upon accessible rodent burrows for estivation habitats (see Semlitsch 1983. Can. J. Zool. 61:616–620). During an 18 February 1996 nocturnal survey for adult California tiger salamanders at a site ca. 2.25 km southeast of Calero Reservoir, Santa Clara County, California, USA, I observed an adult male *Ambystoma californiense* successfully dig through the plugged entrance of a valley pocket gopher (*Thomomys bottae*) burrow. The observation was made on a rainy night between 2131 and 2300 h. The salamander was first observed with its muddied head inserted into a pocket gopher mound. The salamander was then removed, examined, sexed, and placed back in its original position. Subsequent examinations at 15-min intervals revealed the salamander was able to successfully find the burrow entrance and then dig through the mound plug into the pocket gopher burrow. The salamander's digging efforts were aided by a constant steady rainfall, which materially softened the exposed soil of the pocket gopher mound. This observation is significant because it indicates that California tiger salamanders have the ability to burrow out of or into normally closed pocket gopher burrows given sufficiently moist soil conditions. Thus, potential estivation habitat for this salamander is not limited by the surface activities of California ground squirrels (*Spermophilus beecheyi*) or valley pocket gophers in keeping their burrows open at critical times of the year.

My thanks to Norman J. Scott, Jr. for reviewing the manuscript. Permits to conduct salamander surveys were provided by the California Department of Fish and Game.

Submitted by **MARK R. JENNINGS**, National Biological Service, California Science Center, Piedras Blancas Field Station, P.O. Box 70, San Simeon, California 93452-0070, USA, and Research Associate, Department of Herpetology, Califomia Academy of Sciences, Golden Gate Park, San Francisco, Califomia 94118-9961, USA.

PLETHODON CINEREUS (Redback Salamander). **PREDATION.** On 5 June 1993, we observed a *Turdus migratorius* (American robin) at the Mountain Lake Biological Station, Giles Co., Virginia, USA, with an adult *P. cinereus* in its beak. The bird flew ca. 30 m, settled to the ground, and began to peck vigorously at the wiggling, autotomized tail of the salamander. The salamander was less than a meter from the bird. When we approached, the bird flew off. The salamander died within the hour, presumably from injuries suffered while being carried by the bird. Although our intrusion prevented us from observing the culmination of the event, the bird was clearly distracted by the autotomized tail.

Avian predation is not believed to be an important factor in the population dynamics of terrestrial salamanders (Hairston 1980. Am. Nat. 115:354–366). With the exception of the eastern hermit thrush (*Hyloccichla guttata faxoni*), which has been observed feeding *P. cinereus* to its young, salamanders are not mentioned in the diets of thrashers, towhees, and thrushes that forage in the forest litter (Bent. 1964. Life Histories of North American Thrushes, Kinglets and their Allies. Dover Publ., Inc., New York; Hairston 1980, *op. cit.*).

Submitted by **THOMAS L. D. FENSTER**, 4103 Sheridan Street, University Park, Maryland 20781, USA, and Mountain Lake Biological Station, Route 1, Box 105a, Pembroke, Virginia, USA; and **CHARLES B. FENSTER**, Department of Plant Biology, University of Maryland, College Park, Maryland 20742-5815, USA.

PLETHODON DUNNI (Dunn's Salamander). **CANNIBALISM.** Cannibalism has been documented in many amphibians, including several families of salamanders (Crump 1992. *In* Elgar and Crespi, eds. Cannibalism: Ecology and Evolution Among Diverse Taxa, pp. 256–276. Oxford Univ. Press, New York). However, relatively little is known about cannibalism in terrestrial amphibians. Only anecdotal reports of cannibalism in *P. dunni* exist (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. of Idaho Press, Moscow, Idaho. 332 pp.). Herein we report cannibalism of juvenile *P. dunni* by adults under natural conditions.

During Fall 1995 at Fall Creek (Lincoln Co., Oregon, USA, 10 km W Alsea; 360 m) in the Coast Range we stomach flushed 21 adult *P. dunni* and found juvenile *P. dunni* in two (9.5%) gravid females . The first female (SVL 54.5 mm, mass 5.1 g, collected 14 October 1995) regurgitated a juvenile conspecific (SVL 20.6 mm, mass 0.12 g). The second female (SVL 71.4 mm, mass 5.64 g, collected 11 December 1995) also regurgitated a juvenile (SVL 28.5 mm, mass 0.51 g).

The large size difference that exists between juvenile and adult *P. dunni* may promote cannibalism . Cannibalistic individuals may find that conspecifics provide a food source that is easily assimilated and may increase growth and enhance reproduction.

Submitted by **JOSEPH M. RIESECRER, MICHAEL T. ANDERSON, DOUGLAS P. CHIVERS, ERICA L. WILDY, JILL DEVITO, ADOLFO MARCO, ANDREW R. BLAUSTEIN, JOSEPH J. BEATTY**, and **ROBERT M. STORM**, Department of Zoology, Oregon State University, Corvallis, Oregon 97331, USA.

PLETHODON VEHICULUM (Western Red-backed Salamander). **HABITAT.** Nussbaum et al. (1983. Amphibians and Reptiles of the Pacific Northwest, Univ. Press of Idaho, Moscow. 332 pp.) and Stebbins (1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.) reported that *P. vehiculum* is chiefly an inhabitant of moist forests but is generally not associated with sites as wet as those preferred by *P. dunni*. Leonard et al. (1993. Amphibians of Washington and Oregon. Seattle Audubon Society, Washington. 168 pp.) reported that *P. vehiculum* is found associated with free water in Washington but provided no details regarding their use of specific aquatic habitats. The following observations demonstrate that *P. vehiculum* is associated with rocky seeps, springs, and small streams in the northern Puget Trough and Cascade Range foothills of Washington. Furthermore, the absence of *Plethodon dunni* and *Rhyacotriton* in these areas (McAllister 1995. Northwest Fauna 3:81–112) raises the possibility that *P. vehiculum* may shift habitat to more aquatic sites in response to reduced competition from other salamanders.

During Winter 1995–1996, I visited two springs at Fort Lewis Military Reservation, Pierce County, Washington, USA (T18N, RlE, W1/2 S22). Both springs are situated at the base of a steep bluff vegetated by a mature Douglas-fir (*Pseudotsuga menzeisii*) and western red cedar (*Thuja plicata*) forest. During a 45-min search on 29 December 1995, I observed 14 *P. vehiculum* in wet gravel where the spring emerges. As salamanders were uncovered, each attempted to escape by rapidly wriggling through the interstitial spaces in the gravel. On 5 January 1996, I collected two adults (Univ. Mich. FS 07653) and two hatchlings (Univ. Mich. FS 07655) in a 30-min search along a spring-fed creek ca. 1.5 km north of the site visited on 29 December. Both adults were found under rocks in the stream bed and when exposed one dived into the water and swam ca. 15 cm before seeking cover under rocks ca. 6 cm beneath the water's surface. Two hatchlings (15 mm SVL) were found beneath a rock in wet sand on the stream edge. *Dicamptodon tenebrosus* was the only other vertebrate found inhabiting these springs and streams.

Similar observations have been made elsewhere in the northern Puget Sound Basin and in the foothills of the Cascade Range of western Washington. On 8 April 1994, I collected 20 *P. vehiculum* in a 30-min search of a rocky seep at the base of a steep, forested ravine in Olympia, Thurston County, Washington (T18N, R2W, NE1/4 S15). R. A. Nussbaum (pers. comm.) reported a seep in the Green River Gorge, King County, Washington, contained the highest relative abundance of *P. vehiculum* that he has ever observed. An association with rocky seeps has also been reported in the Cascade foothills of Pierce County (Slater. 1936. Mt. Rainier Nat. Pk. Nature Notes 14(4); L. L. C. Jones, pers. comm.).

I thank Michael Adams, Charles Crisafulli, Lawrence Jones, and Ronald Nussbaum for commenting on an earlier draft of this manuscript.

Submitted by **WILLIAM P. LEONARD**, Washington Natural Heritage Program, Department of Natural Resources, P.O. Box 47016, Olympia, Washington 98504-7016, USA.

ANURA

RANA PRETIOSA (Spotted Frog). **BEHAVIOR and REPRODUCTION.** On 23 September 1990 we (WPL and NPL) observed 25 adults, 12 metamorphs, and 2 advanced tadpoles of *R. pretiosa* during a 2.5-h search in a ca. 30 x 35 m fen situated at 1679 m in the Cascade Mountains, Chelan County, Washington, USA (UTM Zone 10, E672,579.4 N5,376,868.0 m). Adults behaved similarly upon our approach—diving into the water from the bank and taking cover in a thick layer of organic detritus. On 26 May 1991 we (WPL and NPL) returned to find both the fen and the surrounding conifer forest covered by ca. 2 m of snow. Only a ca. 1.5 x 2.5 m pool at the inlet channel was free of snow and ice. As we approached we observed ca. 8 *R. pretiosa* dive below the surface and swim out of sight beneath the snow pack covering the remaining surface of the fen. In this same pool, we observed a pair of *R. pretiosa* in amplexus sitting among sedges (*Carex nebrascenisis*) in ca. 5 cm deep water. The pair never moved from its original position despite our descending the steep, 2 m high snow bank and approaching within ca. 0.3 m. No eggs were observed, indicating that oviposition had not begun. Given both the depth and complete coverage of the surrounding forest with snow, these individuals had surely overwintered in the fen.

On 23 May 1992 between 1056 and 1130 h, we (WPL, RMS, PEP) again visited this site and found the forest surrounding the pond covered by ca. 1 m of snow. We found two ca. 200 m^2 areas of the fen to be snow and ice free—one at the inlet channel at the east end and one around the outlet channel at the west end. At the eastern side of the fen we observed ca. 20 males floating fully exposed at the surface and 35 freshly deposited egg masses in a ca. 4 m^2 area vegetated by sedges in 20–25 cm deep water. The water temperature at the oviposition site was 7.5°C. A conspicuous churning of water was caused when a male appeared to amplex another male; upon contact, the second male jumped up, apparently stimulating the entire congregation of males to jump about in a burst of short leaps. On two occasions, the males were heard calling as a group for ca. 7–12 sec followed by prolonged quiescent periods. The calls consisted of a series of 5–7 rapid, weak notes and were first thought to be a woodpecker tapping on a tree in the adjacent forest. A second breeding congregation of ca. 20 males and a pair in amplexus was found on the north side of the east pool. This group was also among sedges in 5–10 cm of water.

These observations demonstrate that *R. pretiosa* overwinter in breeding ponds in the Cascade Mountains in Washington, thus enabling breeding to commence as soon as a small portion of the breeding pond is free of snow and ice. This behavior would appear to provide a significant reproductive advantage to populations of *R. pretiosa* at high elevations in the Cascade Mountains where the snow-free period may last for as little as three months.

RANA PRETIOSA (Spotted Frog). **TOE CLIPPING EFFECTS.** Toe-clipping has been the most widely employed technique for marking individual amphibians since Bogert (1947. Am. Mus. Novit. 1355:1–24) introduced the method. Recently there has been considerable concern worldwide regarding ethical and survivorship implications of toe-clipping (Halliday 1994. Froglog 10:2–3). There is, however, a paucity of direct evidence indicating that toe-clipping causes mortality. The dearth of such reports may stem from biologists' reluctance to report findings that indicate their work impinges on the life of their subjects and, as a result, potentially biases their data (Reaser 1995. Froglog 12:1–2).

The study most often cited as evincing a causal relationship between toe-clipping and amphibian mortality (Clark 1972. Copeia 1972:182–185) does not provide substantive data (Reaser 1995, *op. cit.*). Two studies do, however, illustrate sub-lethal effects of toe-clipping that could influence amphibian survivorship and fitness: Underhill (cited by Honegger 1979. Int. Zoo Yb. 19:4–22) documented weight loss in leopard frogs following toe amputation; Golay and Durrer (1994. Amphibia-Reptilia 15:81–96) reported that in 18% of the natterjack toads they mark-release-recaptured, toe-clipping resulted in metastatic infection and necrosis, sometimes involving the entire limb.

As part of a multi-year study of *Rana pretiosa* in the Great Basin, we individually marked, following the scheme of Donnelly (1989. Ecol. Monogr. 59:207–221), 122 *R. pretiosa* within a multi-pool complex of Indian Creek, Nye Co., Nevada, USA on 26 July 1994. With the aid of finger-nail clippers, one to two toes were excised per animal just above the toe base. Toe-nail clippers were cleaned with isopropyl alcohol following each excision. The frog wounds were treated with anti-bacterial ointment, and animals were immediately released at the point of capture. Frogs were observed by RED for a total of 47.5 h over the 10-day period between 29 July–8 August 1994. The frogs did not exhibit any signs of infection and no mortality was detected. However, inflammation in several of Golay and Durrer's (*op. cit.*) toads was not evident until at least one month following surgery.

On 26 July 1995 and 30 July 1995 four frogs marked in 1994 were recaptured by JKR at this site. On 26 July 1995 a fifth frog that had been marked at the Indian Creek site was located 5 km away. Individual marks were easily distinguished on these frogs and the clipped toes were well-healed, without scarring. Comparison of SVL and weights between capture dates indicated that three frogs showed marked growth, while two frogs were measured (possibly due to observer bias) slightly smaller than original size (3.8 to 6.9 cm,4.5 to 37g;4.0 to 5.8 cm,4.0 to 20 g; 3.5 to 5.7 cm, 4.0 to 15.0 g; 6.5 to 6.4 cm, 30 to 28 g; 7.0 to 6.5 cm, 34 to 31 g). All recaptured frogs were female; the two heaviest frogs appeared gravid.

Two unmarked females (5.7 cm, 10.5 g; 5.8 cm, 22 g) were found in the ditch with the fifth recaptured frog. One toe was excised for skeletochronological analysis from all three frogs and the animals were immediately released. The nail clippers were again treated with alcohol, but anti-bacterial ointment was not applied. On 9 August 1995 the three frogs were recaptured within the ditch. The recently clipped toe of the frog originally marked in 1994 was slightly red and inflamed to twice its normal width (Fig. 1). The wound had healed over, and the animal otherwise appeared in good health; it measured 6.5 cm and 34 g and was still appeared gravid. Both of the other frogs had well-healed toes without signs of infection. These frogs grew by 0.3 cm/11.5 g and 0.4 cm/1 g. An attempt to recapture the frogs on 14 September 1995 failed.

For birds it is widely held that mortality due to capture and marking is acceptable as long as it does not exceed one percent of the sample. However, determining actual rates of mortality is impossible unless marked individuals are followed consistently for extended time. In this study, fewer than one percent of the animals marked showed signs of infection and no mortality was detected. The acceptability of these findings should be part of the decision-making process employed by anyone considering toe-clipping as marking strategy.

In evaluating amphibian population trends, especially in instances of suspected decline, we must be able to interpret the influence of study on the target organisms. Regardless of how cautious and concerned biologists are, it is not valid to assume that animals are not impacted by those who study them. Controlled studies need to be undertaken on the effects of toe-clipping on amphibians. However, accounts such as reported here can lend substantial information to the general debate on toe-clipping, especially if these reports are amassed for a variety of species. We encourage herpetologists to report observations of the effects of any marking scheme on amphibians. Because marking methods vary greatly, authors should clearly state the procedures followed.

We thank Richard Seymour and Michael Westphal for field assistance. Funding was provided to JKR by a Graduate Research Fellowship from the Department of Biological Sciences of Stanford University, the Nevada Biodiversity Research and Conservation Initiative, the Morrison Institute for Population and Resource Studies, and the Theodore Roosevelt Memorial Fund. RED was supported by an Undergraduate Research Opportunities Grant of Stanford University and the Nevada Biodiversity Research and Conservation Initiative. Research followed animal welfare protocols of the University of Nevada.

RANA PRETIOSA (Spotted Frog). **VAGILITY**. *Rana pretiosa* has traditionally been considered a highly aquatic species that is much more closely associated with water than other ranids (Dumas 1966. Copeia 1966:60–74). *Rana pretiosa* requires aquatic habitats for breeding, feeding, hibernation, and escape from predators (Licht 1986. Amer. Midl. Nat. 115:239–247; Morris and Tanner 1969. Great Basin Nat. 29:45–81; Turner 1960. Ecol. Monogr. 30:251–278). Biologists have theorized that since *R. pretiosa* is so dependent upon aquatic habitats, it is unlikely that individuals travel far from water (Bissonette and Larson 1991. Utah Coop. Fish Wildl. Res. Unit Misc. Rep. 91:1–20), althoughTurner (*op. cit.*) found that *R. pretiosa* will occasionally move short distances (tens to hundreds of meters) overland. *Rana pretiosa* studied by Carpenter (1954. Copeia 1954:197–200) and Turner (*op. cit.*) wandered within a limited region (tens to thousands of square meters), generally returning to the vicinity of initial capture. Marked *R. pretiosa* in Hollenbeck's (1976. J. Colorado-Wyoming Acad. Sci. 8:72–73) study did not exhibit behavior indicative of a restricted home range.

As part of a three-year study of *R. pretiosa* in the Great Basin, 122 individuals were uniquely marked by toe-clipping within a 400 m, multi-pool complex of Indian Creek, Nye Co., Nevada, USA on 26 July 1994. Four marked animals were recaptured at the same location one year later. A fifth frog (6.5 cm, 31 g, F) was recaptured 26 July 1995 in a water-filled, roadside ditch 5 km straight-line distance upstream from the point of original capture. Two unmarked *R. pretiosa* (5.8 cm, 22 g, F; 5.7 cm, 10.5 g, F) and approximately 50 *Spea intermontana* metamorphs were also present. Average ditch depth was 15 cm, maximum depth was 30 cm. Water temperature was 23°C, and air temperature was 27°C. Sagebrush dominated the site. Straight-line distance to the ditch from Indian Creek was 0.5 km.

The 5 km travelled by the recaptured frog far exceeds previous records. In a mark-recapture study of *R. pretiosa* in Yellowstone National Park during 1953–1959, Turner (*op. cit.*) found that maximum movement between successive captures was 1260 m straight-line distance between 16 September 1954 and 5 August 1955. Other emigrations, ranging from 375–1250 m were also recorded. Maximum rates of movement ranged from an average of 61.5 to 186 m/day. At Jackson Hole, Wyoming, in Grand Teton National Park between July and August 1951, Carpenter (*op. cit.*) discovered that marked *R. pretiosa* moved an average of 1.5 straight-line m/per day (N = 91) with an average maximum of 6.0 straight-line m/per day. The maximum total distance a frog moved was 44.4 straight-line m in a 148-day period (3.3 m/day). Hollenbech (*op. cit.*) found that movements of *R. pretiosa* adults to and from breeding areas ranged from 41–443 straight-line meters; the most rapid movement being 8.9 m/day. Generously assuming 210 days of activity, the recaptured frog that moved 5 km would have travelled an average of 23.8 straight-line m/day.

Carpenter (*op. cit.*) believed that extreme downstream movements might be accounted for by swift currents displacing animals after heavy rains. Nye County, Nevada did experience intensive snow-melt flooding in 1995 and animals from the Indian Creek site might have been carried downstream into regions that are usually dry. However, the 5 km frog was found upstream, making its movement even more remarkable. The region of study is very sparsely populated, and it is extremely unlikely that the frogs reached the ditch with human assistance. It is plausible that *R. pretiosa* take advantage of "wet years" by dispersing into potentially colonizable regions, across a landscape that is usually too dry to be inhabited. Small, ephemeral creeks in 1995 may have served as corridors for movements between Indian Creek and the ditch. One other site, an isolated pooled seep, that was frogless in 1994 was found to be occupied by a single *R. pretiosa* in 1995 (6.3 cm, 24 g, M). This site was at 6 km and 7 km straight-line distance from the nearest source populations to the north and south, and was loosely connected to the two sites by ephemeral seeps and creeks (dry in most of 1994, wet to midsummer in 1995) within a sagebrush matrix.

These observations are important because they demonstrate that amphibians can move extreme distances within harsh environments and that sink habitats (sensu Pulliam 1988. Am. Nat. 132:652–661) may serve as "stepping stones" to facilitate the movement of animals to colonizable source habitats. Sink habitats with permanent water supply could also act as refugia when "wet year" dispersing frogs are stranded by the drying landscape.

TESTUDINES

CLEMMYS INSCULPTA. (Wood Turtle). **REPRODUCTIVE BEHAVIOR.** The normal position of the sexes during mating in freshwater turtles is male plastron to female carapace with male above the female (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 576 pp.). Plastron to plastron mating position seldom has been reported. Tronzo (1993, Herpetol. Rev. 24:149) observed mating in *C. insculpta* on 11 October 1992 in Pennsylvania during which the male grasped the female in a plastron to plastron position with the male below. He surmised that moving the pair from land to water and tapping on the male's carapace may have influenced the male's movements and his unusual position. At 1125 h EDT on 23 April 1995 a mating pair of *C. insculpta* was observed on the bottom in clear, shallow (ca. 25 cm) water in 15 Mile Creek, Green Ridge State Forest, Allegany County, Maryland, USA. The male was above the female in normal position but the female was on her back so that the plastrons of the two turtles were in contact. The male had clasped the female around her carapacial margin with all four feet and was heard thumping his shell against hers several times during the observation period (1 h 3 min). Biting of and around the female's head occurred frequently. The male took a breath three times but the female was not allowed to reach air in the time observed. Copulatory intromission was not discernible, as the turtles were not disturbed. Except for the plastron to plastron position, these observed mating behaviors are similar to those described in detail by Kaufmann (1992, Herpetol. Monogr. 6:1–25). Our observation establishes that this behavior is natural and that the interference with a mating pair by Tronzo (*op. cit.*) may not have been a major factor in causing the plastron-to-plastron mating position that he observed.
